Collaboration

Joint Experimental-Theoretical  
Physics Seminar

April 12, 2013

# Charm Mixing Overview

(More extensive overview available on the PDG web page)

# Neutral Meson Mixing

- Particle - antiparticle oscillation
- Production eigenstates  $\neq$  mass eigenstates

$$|D^0\rangle = \frac{1}{\sqrt{2}} (|D_1\rangle + |D_2\rangle) \quad |\bar{D}^0\rangle = \frac{1}{\sqrt{2}} (|D_1\rangle - |D_2\rangle)$$

Assuming no CP violation

- Time evolution of mass eigenstates

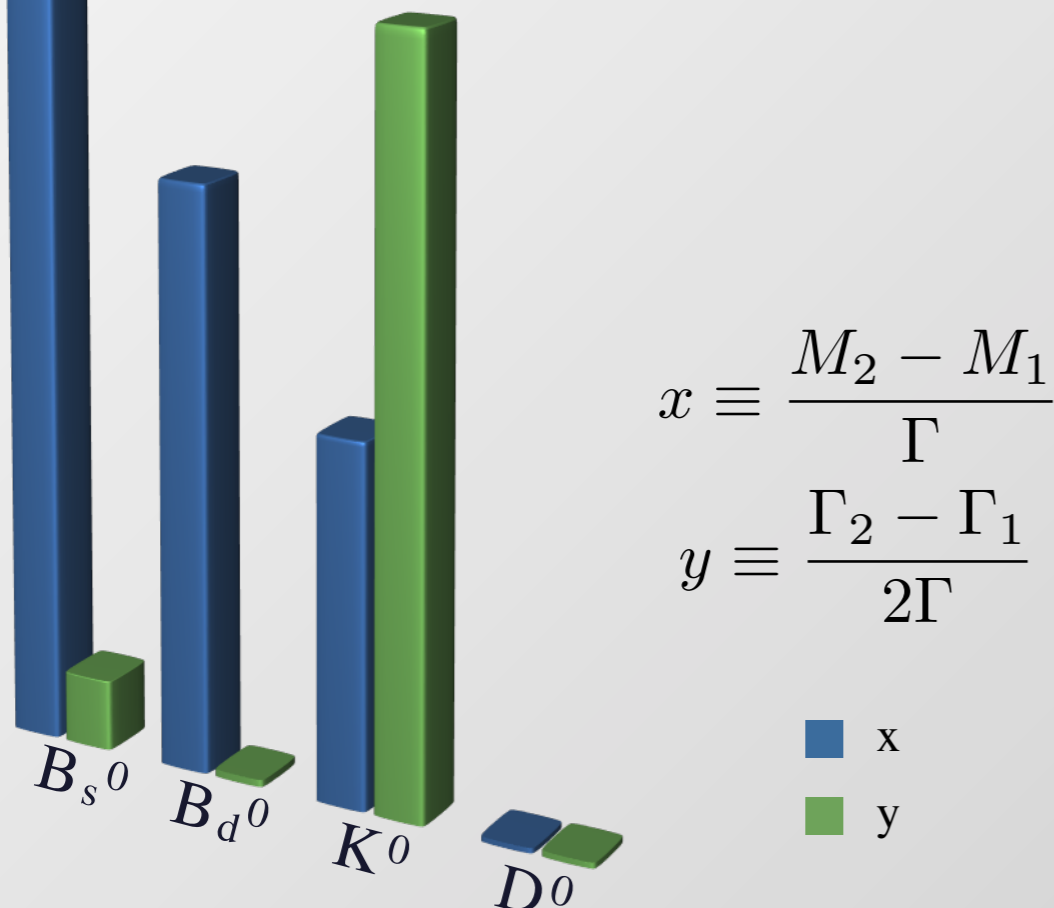

$$i\frac{\partial}{\partial t} |D_{1,2}(t)\rangle = \left( M - \frac{i}{2}\Gamma \right) |D_{1,2}(t)\rangle$$

$$|D_{1,2}(t)\rangle = |D_{1,2}(0)\rangle e^{-t\left(\frac{1}{2}\Gamma_{1,2} + iM_{1,2}\right)}$$

# Meson Mixing

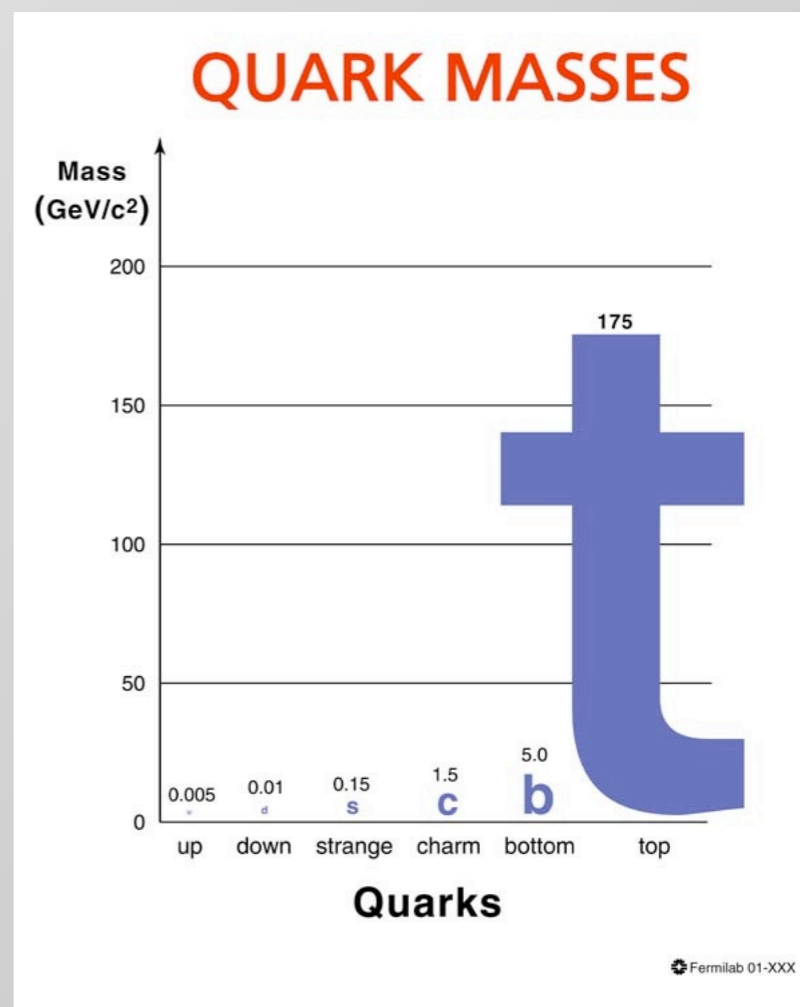

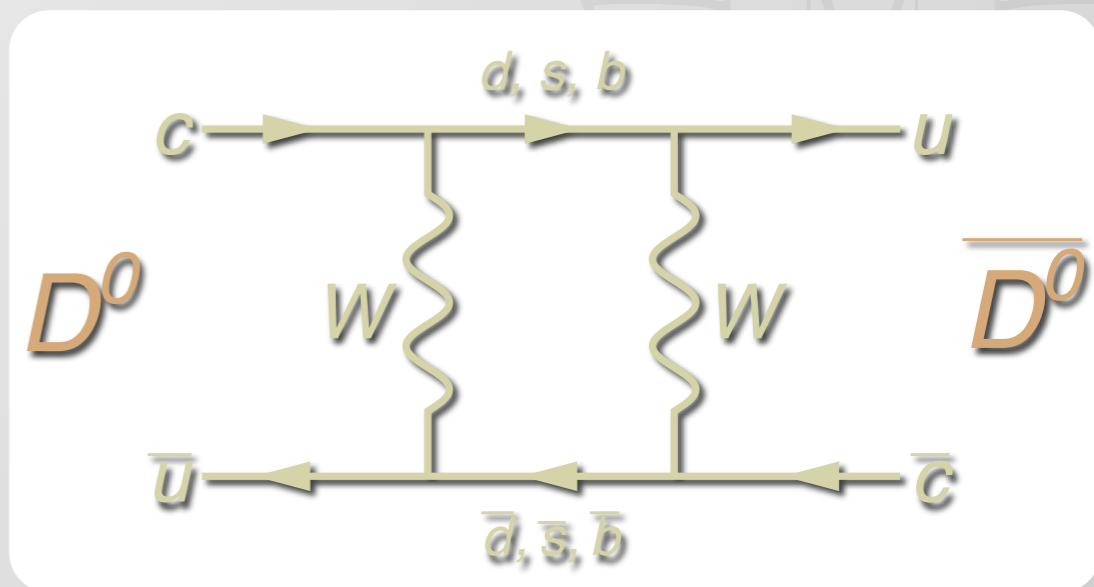

Mixing	x	y
$B_s^0$	26.6	0.092
$B^0$	0.77	0.009
$K^0$	0.474	0.997
$D^0$	0.0065	0.0073

- Charm mixing is small
- Despite D mesons being seen before B mesons, charm mixing was only observed recently
  - kaon mixing seen 1962
  - beauty mixing seen 1987
  - $B_s$  oscillations observed 2006
  - first evidence of charm mixing was in 2007
  - first single measurement observation of charm published March 2013 (LHCb)

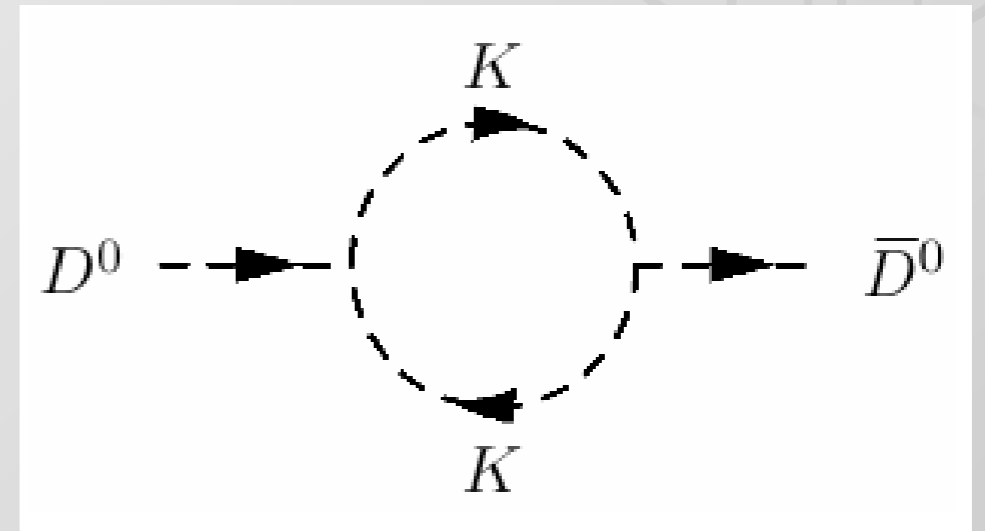

# Calculating Mixing

- Kaon and Beauty mixing due to contributions from the box diagrams
  - superheavy quarks (i.e. top) destroying GIM cancellations
- For charm, those contributions are small
  - $O(10^{-5})$  or less
  - down-type quarks (no top)

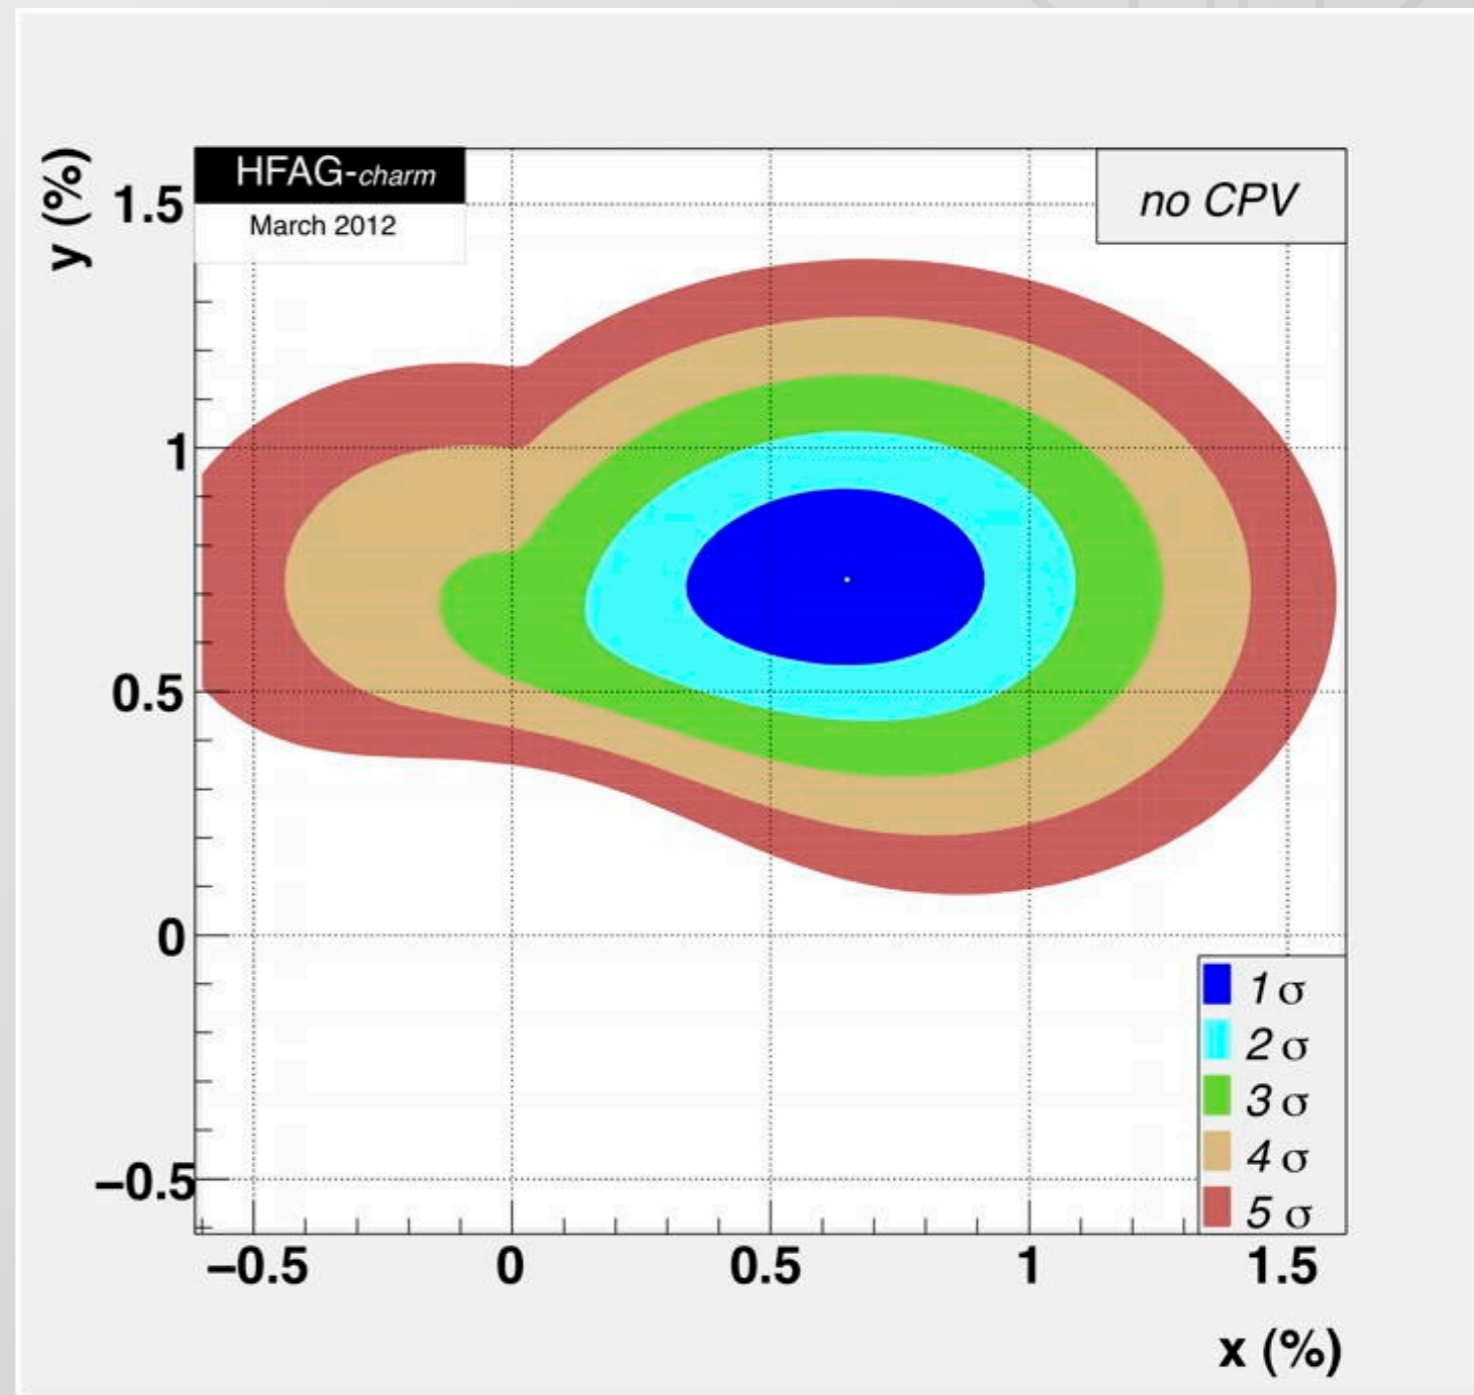

# Calculating Mixing

- Long-distance contributions are important for charm mixing
  - $O(10^{-2})$  or less
  - $D^0$  and  $\bar{D}^0$  can decay to common hadronic states like  $KK$  or  $\pi\pi$
- harder to get theory predictions
  - non-perturbative, model dependent
  - only mixing involving up-type quarks
  - CP violation studies (New Physics)
  - as results get more precise, can reduce the number of viable theory models
    - also relate mixing to rare decays  
(like  $D^0 \rightarrow \mu\mu$ )

# Charm Mix Measurements

- Heavy Flavor Averaging Group has combined all  $D^0$  decay modes and experimental results
  - semi-leptonic decays,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ ,  $K^+\pi^-\pi^+\pi^-$ , lifetime differences ( $KK$ ,  $\pi\pi$ ),  $K^0\pi^-\pi^+$ ,  $K^0K^-K^+$
- The no-mixing hypothesis excluded at  $10.2\sigma$  significance
- Only a few measurements have exceeded  $3\sigma$

# Charm Mixing with $D^* \rightarrow \pi_s D^0, D^0 \rightarrow K\pi$

# $D^*$ , $D^0$ , $K\pi$

- For this analysis, need:

- Proper decay time for time evolution
- Identify charm flavor at production
- Identify flavor at decay

- $D^* \rightarrow \pi_s D^0$ ,  $D^0 \rightarrow K\pi$

- Measure decay length from the beamline

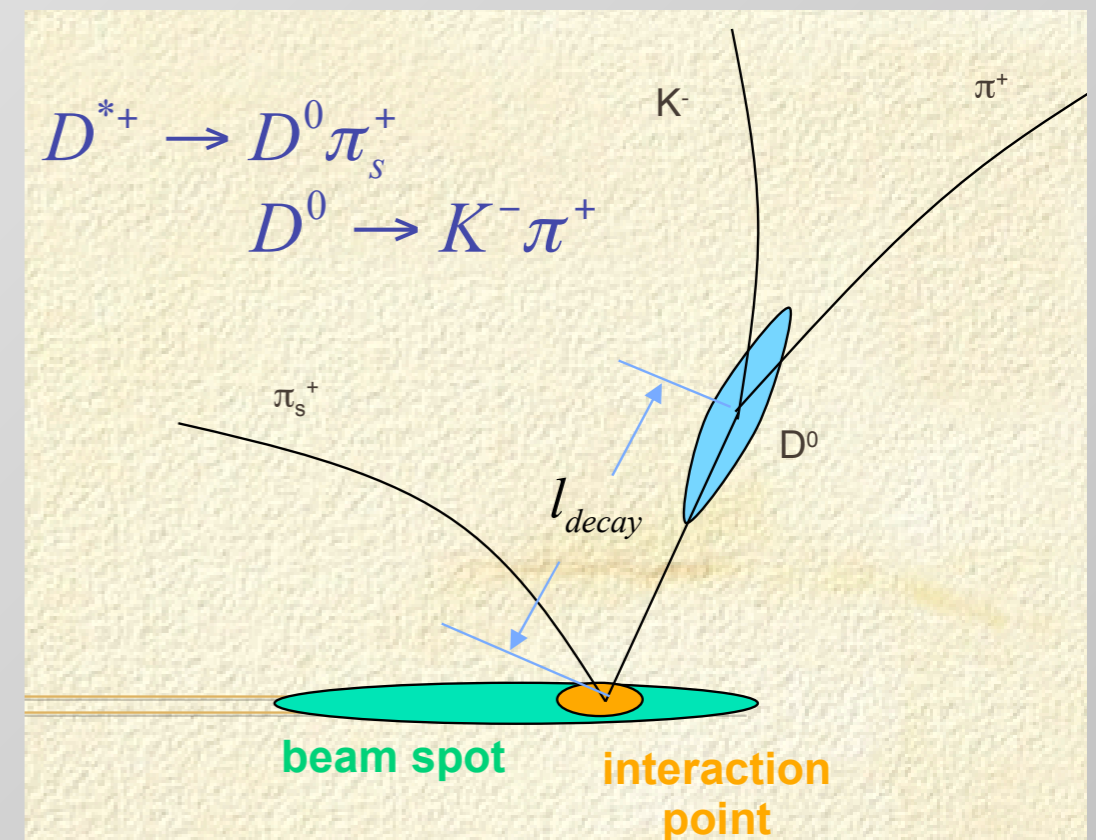

- $\pi_s^+ \mapsto D^0$

$$\pi_s^- \mapsto \bar{D}^0$$

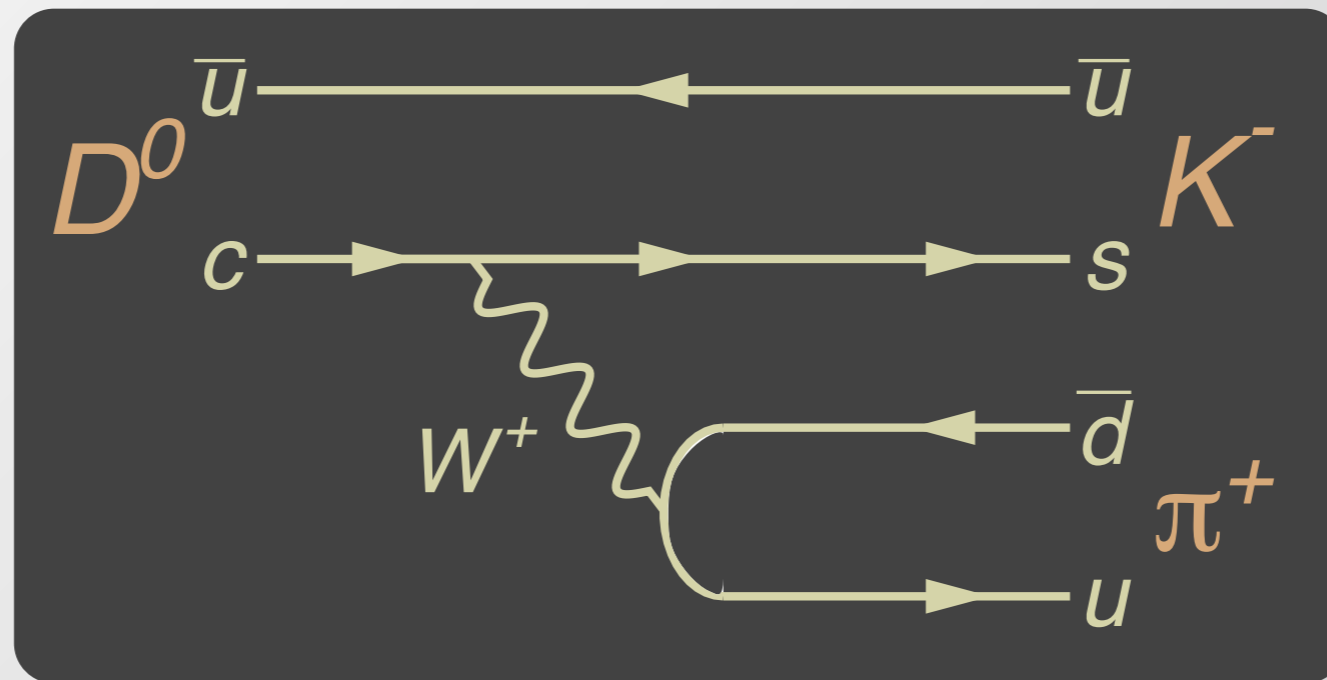

- $K^+\pi^-$  or  $K^-\pi^+$

“s” stands for softer momentum

Requiring a  $D^*$  also improves  
signal:background

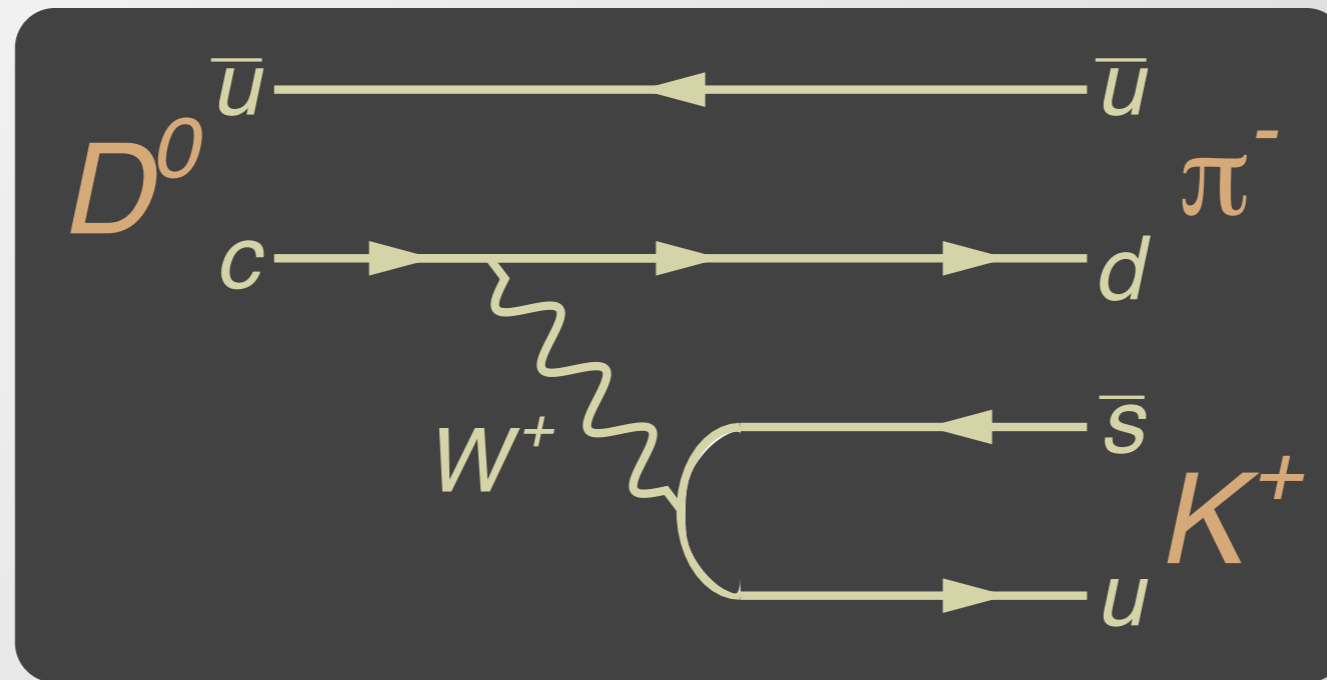

# Lingo: “Right-sign”

- “Right-Sign” events have pions with the same charge
  - $D^{*+} \rightarrow \pi_s^+ \pi^+ K^-$
  - Cabibbo favored (CF)  $D^0$  decay

# Lingo: “Wrong-sign”

- “Wrong-Sign” events have pions with opposite charge
  - $D^{*+} \rightarrow \pi_s^+ \pi^- K^+$
  - Doubly Cabibbo suppressed (DCS) decays
  - Mixing:  $D^0 \Leftrightarrow \bar{D}^0$ , followed by CF decay
- RS:WS roughly 300:1

# Decay Rate Ratio

- With  $x, y \ll 1$  and assuming no CPV, the time-dependent ratio of WS to RS events can be approximated by

$$R(t/\tau) = R_D + (t/\tau) \sqrt{R_D} y' + (t/\tau)^2 \frac{x'^2 + y'^2}{4}$$

DCS to CF ratio

Interference

Mixing

(note:  $R_D \sim O(0.3\%)$ )

- Formula uses  $x', y'$  instead of  $x, y$

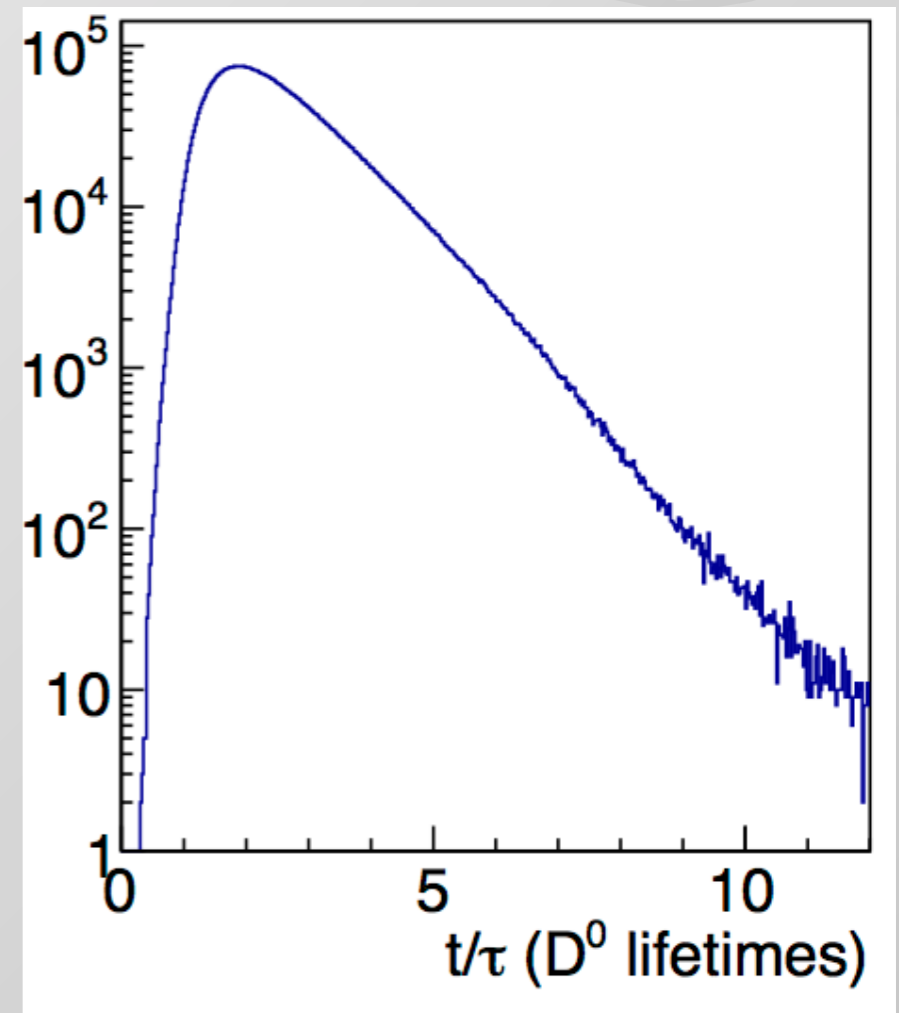

$$x' = x \cos \delta_{K\pi} + y \sin \delta_{K\pi}$$

$$y' = y \cos \delta_{K\pi} - x \sin \delta_{K\pi}$$

- Strong phase difference  $\delta_{K\pi}$  between CF and DCS amplitudes
- $x^2 + y^2 = x'^2 + y'^2$

# Misc Notes

- Including charge conjugate decays ( $D^{*+}$  and  $D^{*-}$  combined)
- simplifies systematic errors in the WS/RS ratio
- Events divided into 20 bins of decay time, ranging from 0.75-10  $D^0$  lifetimes
- Bin width gets wider as the decay time increases
- Event-weighted mean time for each bin, determined from RS  $D^*$
- Analysis precision is limited by the number of WS  $D^*$

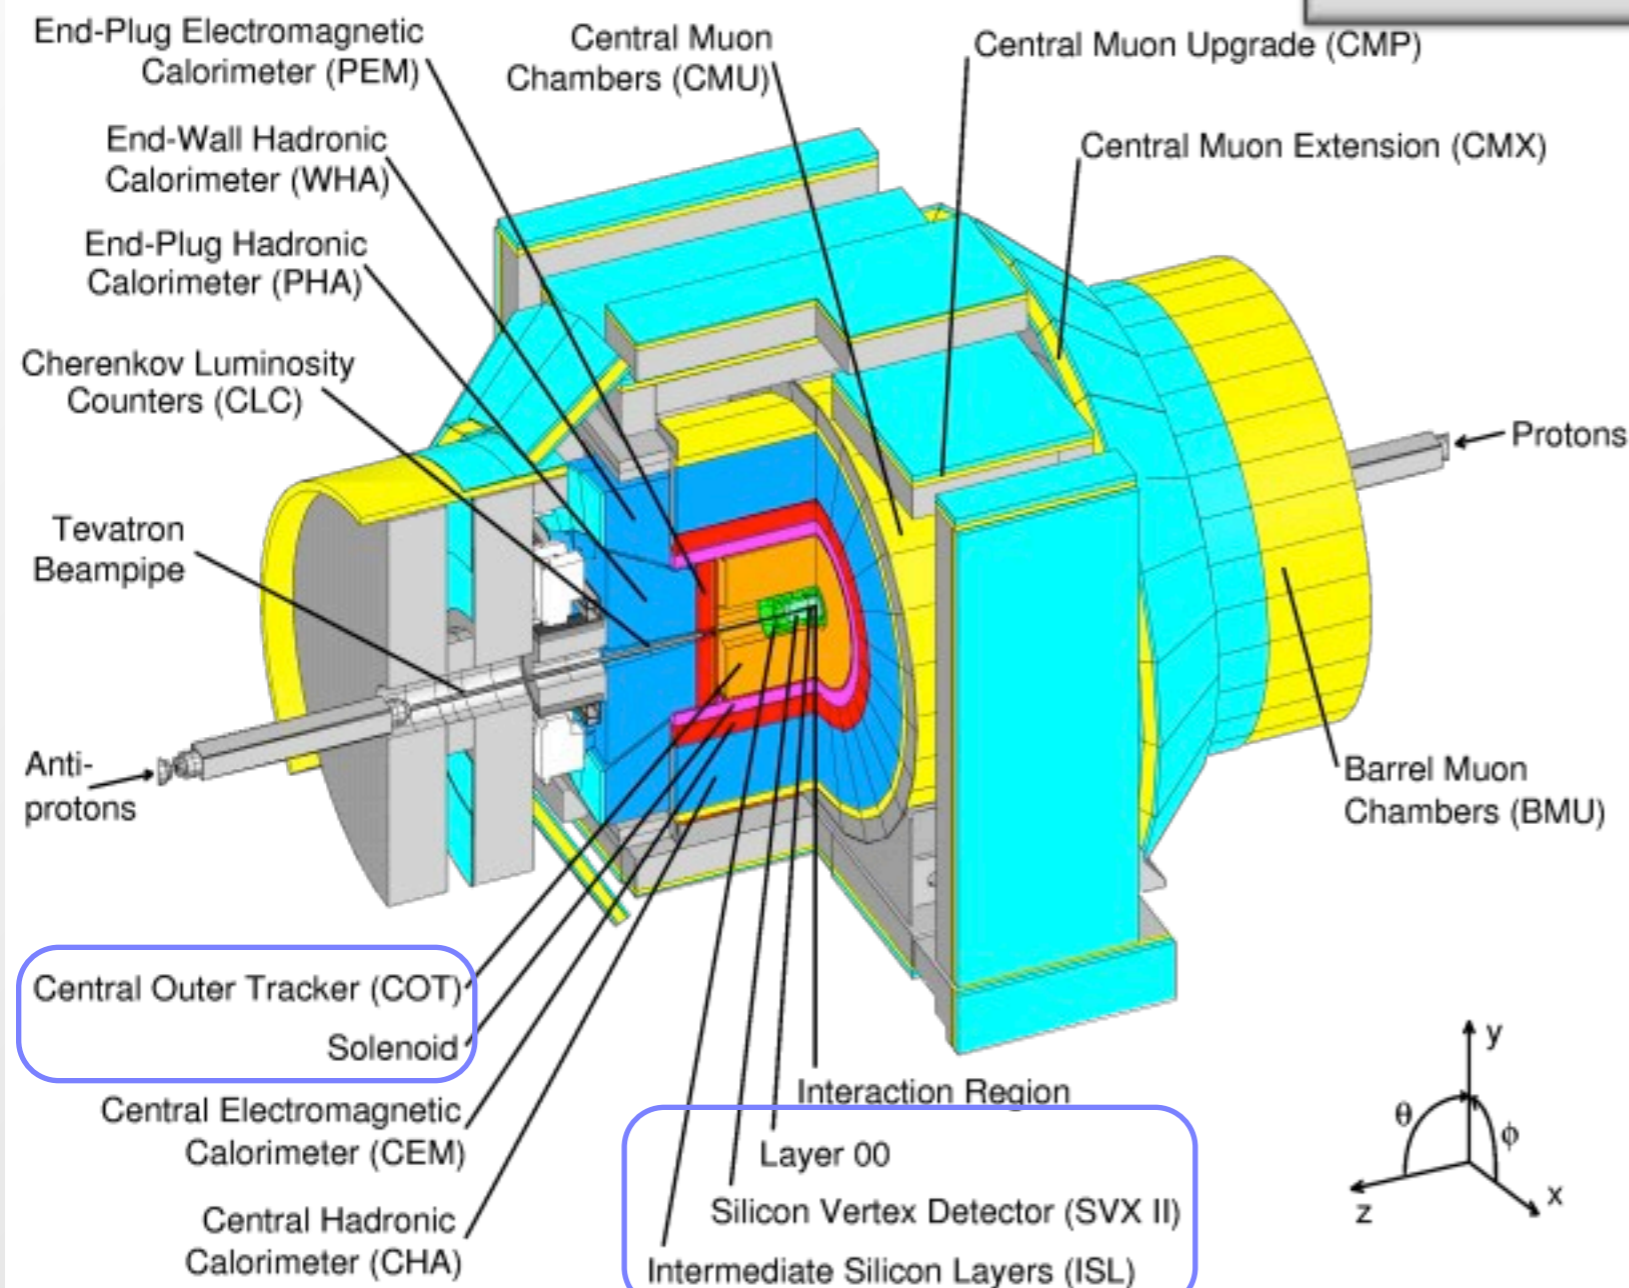

# CDF Event Selection

# CDF II Detector

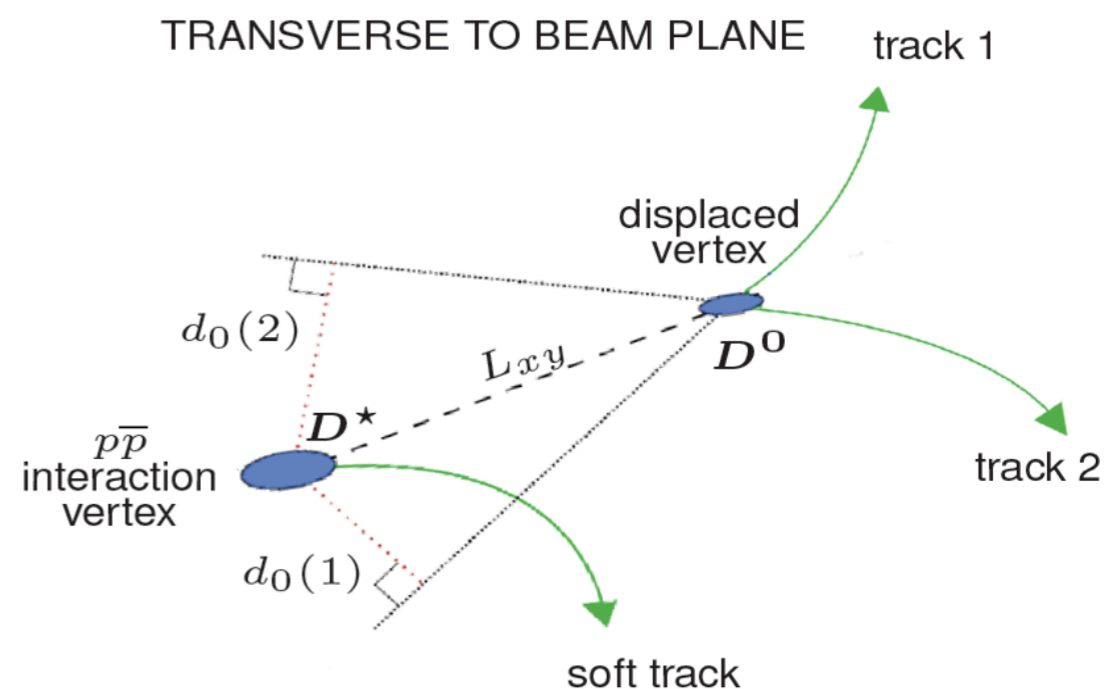

## The CDF II Detector

- Data collected from Feb 2002 - Sep 2011
- $\int L \approx 9.6 \text{ fb}^{-1}$  at  $\sqrt{s} = 1.96 \text{ TeV}$
- Looking at fully reconstructed  $D^0$  decaying to charged  $K$  and  $\pi$
- silicon vertex detector surrounded by wire drift chamber (COT) in 1.4T solenoid (central tracking)
- Particle identification using energy loss ( $dE/dX$ ) in the COT

# Hadronic Trigger

- CDF used a dead-timeless, high rate trigger system
- This analysis uses the hadronic trigger that requires two oppositely charged tracks in COT+SVX from a displaced vertex
- Optimized for  $B$  decays, but has good charm acceptance
- The trigger tracks are used to form the  $D^0 \rightarrow K\pi$  candidates
- Additional tracks found off-line to form  $D^{*+} \rightarrow \pi_s^+ D^0$  candidate

# Candidate Composition

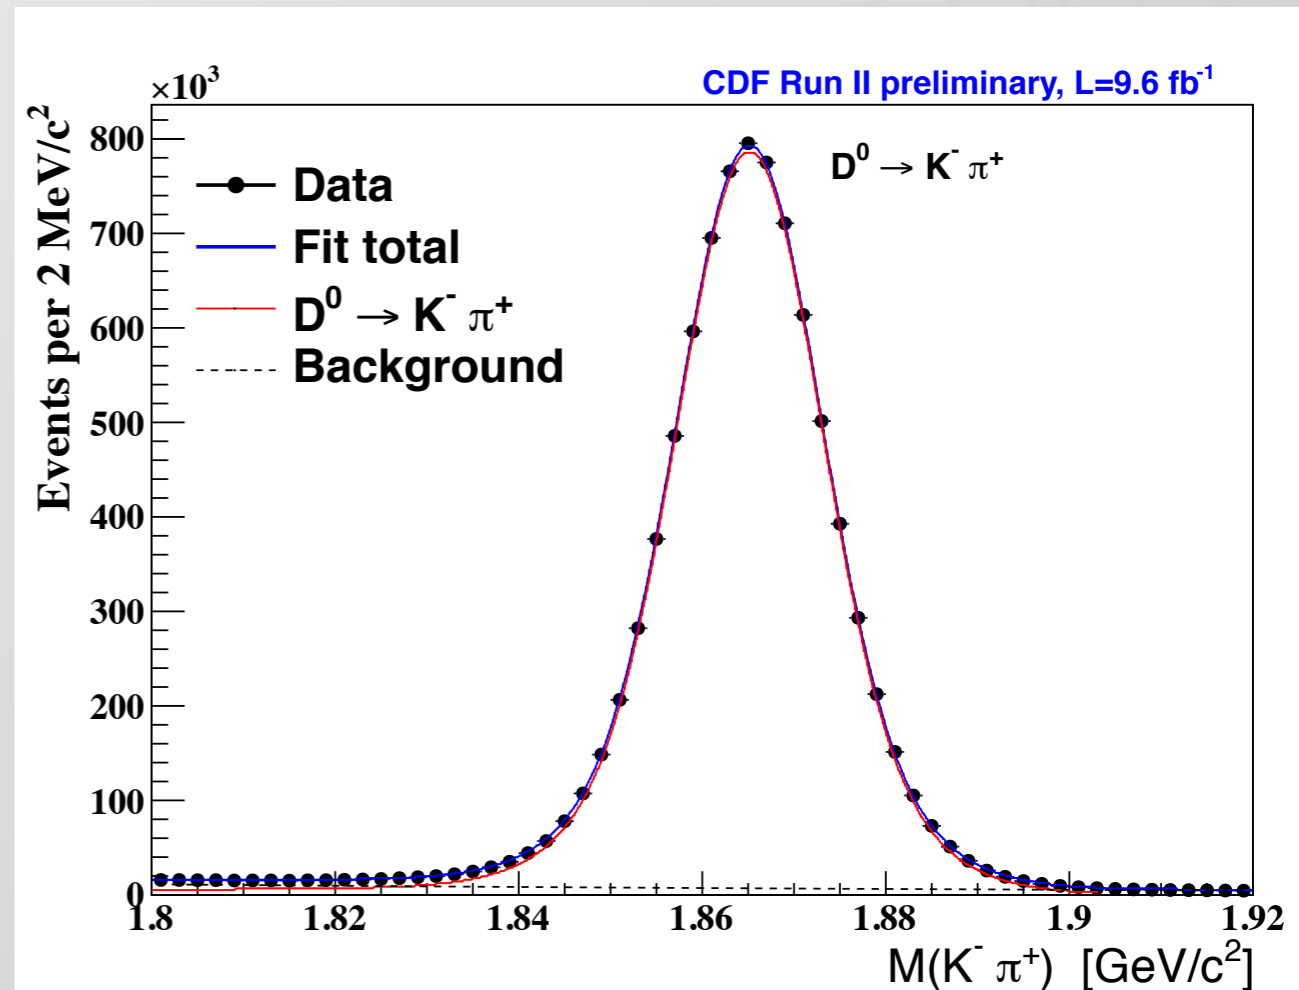

- $D^*$  produced at the beamline interaction <-- SIGNAL
- $D^*$  from secondary decays, like B mesons
  - Will have different impact parameter ( $d_0$ ) from signal
- fake  $D^*$  candidates:  $D^0 + \text{random track}$ 
  - Different  $\Delta M$  [  $= M(\pi_s K \pi) - M(K \pi) - M(\pi_s K \pi)$  ] from real  $D^*$
- $D^0 \rightarrow K \pi$  incorrectly reconstructed as  $\pi K$ 
  - particle identification and  $K \pi$  mass distribution different from  $D^0$
- Other  $D^0$  backgrounds
  - $D^0 \rightarrow KK$ ,  $D^0 \rightarrow \pi \pi$ , partially reconstructed charm, combinatoric background
  - smooth  $K \pi$  distribution (non-peaking)

# Basic Selection Cuts

- The detached vertex trigger, by itself, gives us a clean CF  $D^0$  signal

- Basic selections:

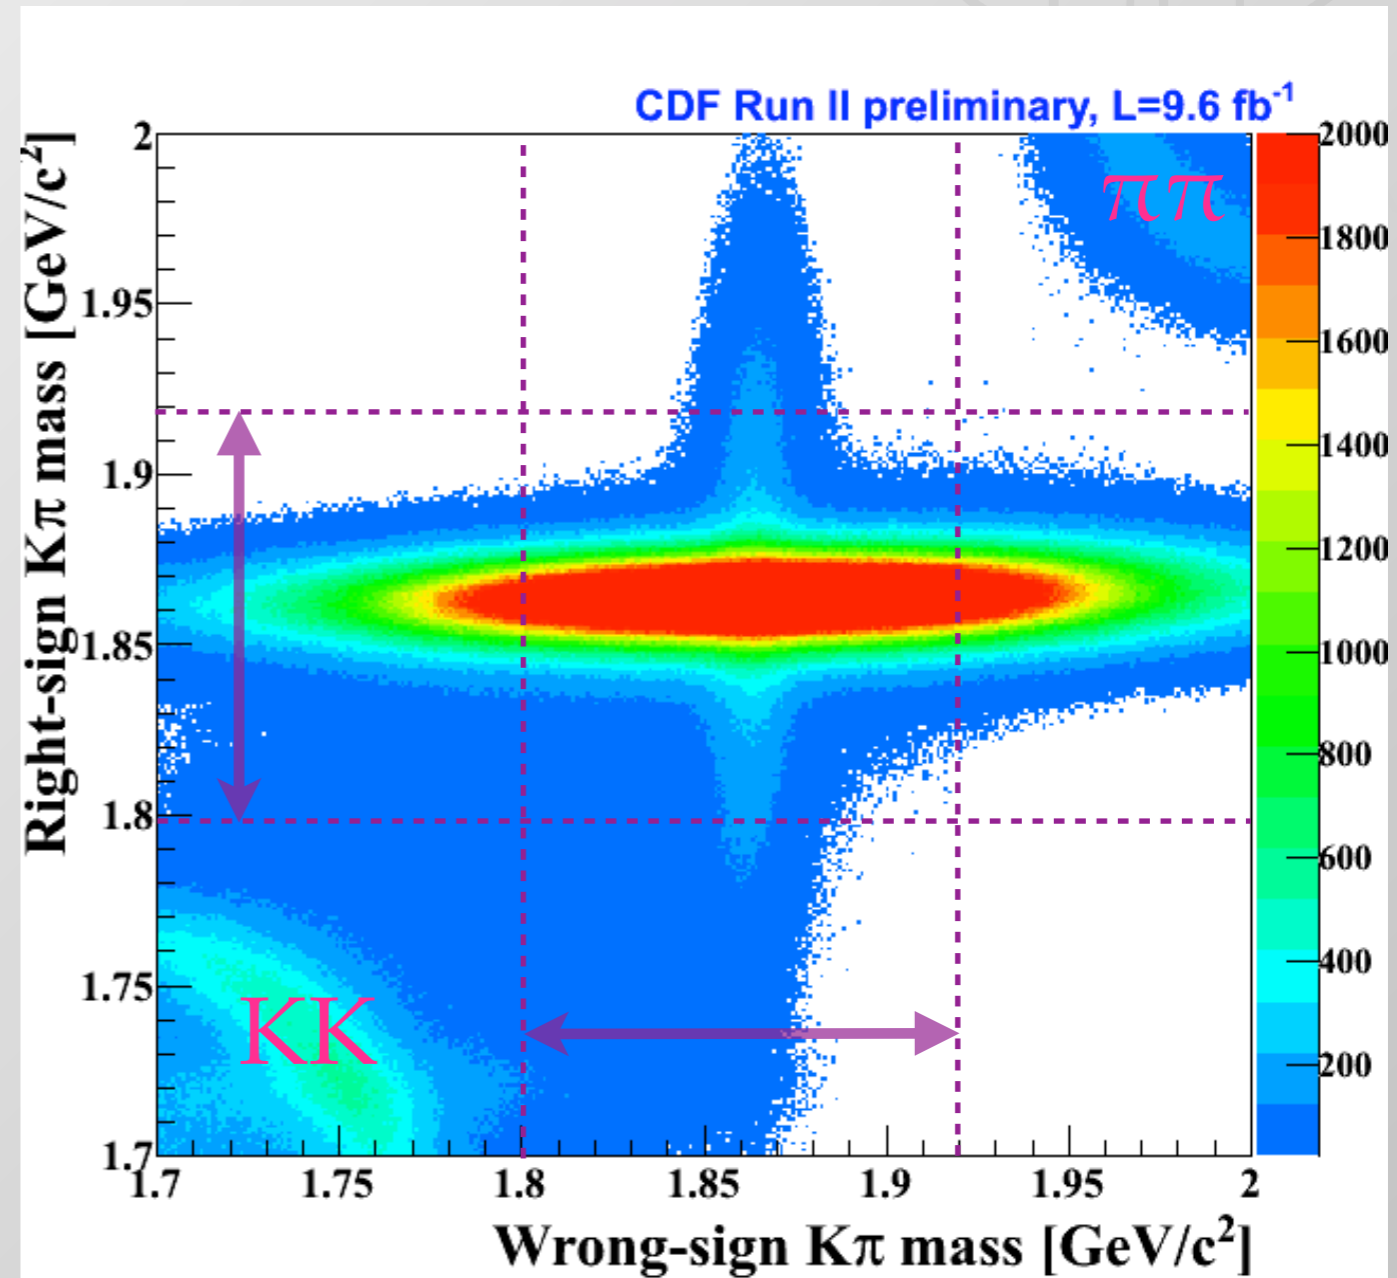

- $\Delta M < 30 \text{ MeV}/c^2$ 
  - Fewer fake  $D^*$  candidates
- $D^0$  impact parameter  $d_0 < 60 \text{ } \mu\text{m}$ 
  - Reduce  $D^*$  from secondaries
- $\pi_s$  track must pass near beamline
  - Reduce obvious fake combinations
- $\pi_s \ 0.4 < p_T < 2.0 \text{ GeV}/c^2$ 
  - reliable tracking, below trigger threshold
- after all selections (including following slides), only include events with a single  $D^*$  candidate

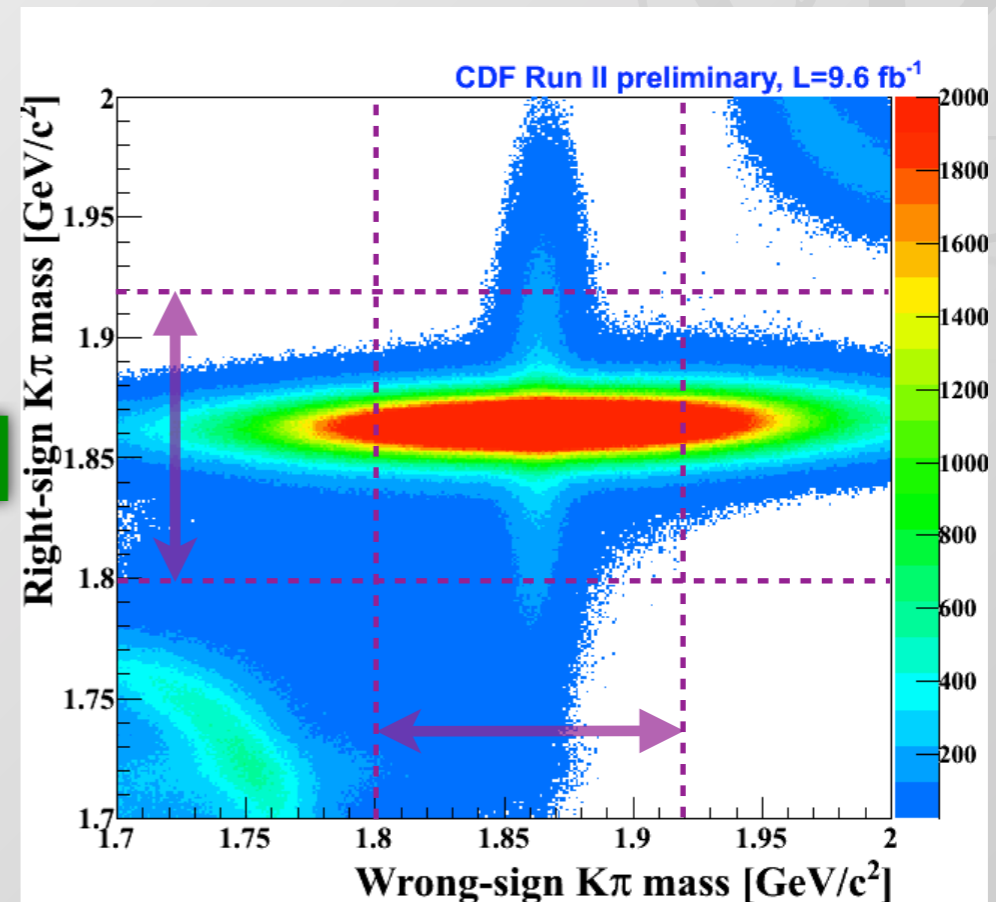

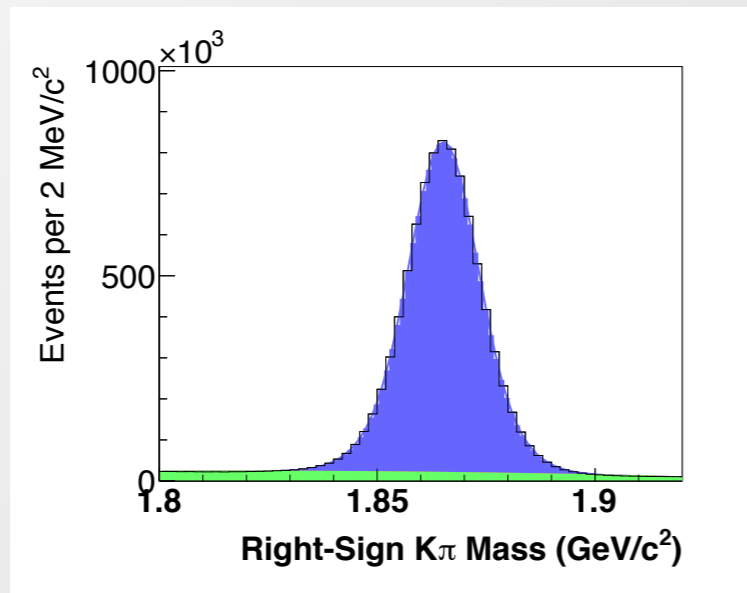

$>8 \times 10^6$  time integrated RS  $D^0$   
(after all selections)

# RS and WS Data

- $D^0$  candidates start with both  $K\pi$  and  $\pi K$  particle assignments possible
- limit mass range to  $1.8 < m_{K\pi} < 1.92 \text{ GeV}/c^2$ 
  - Excludes  $D^0 \rightarrow KK, \pi\pi$

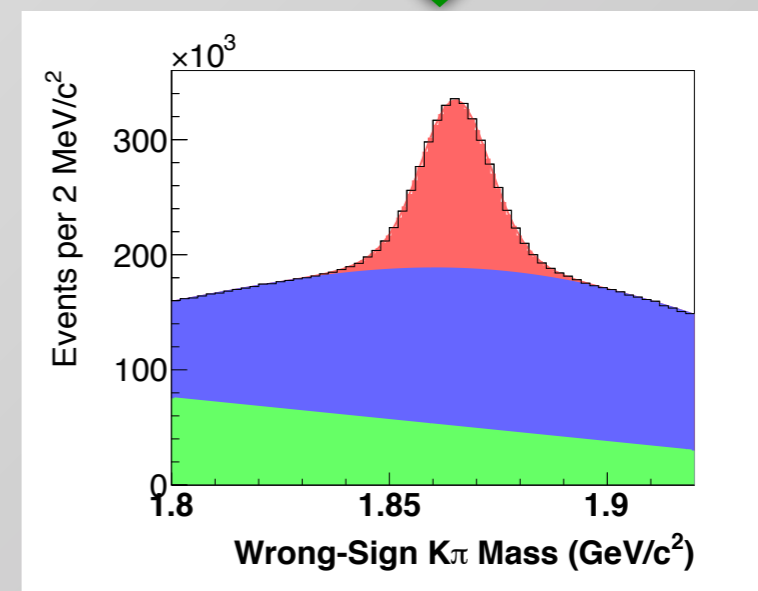

# RS and WS Data

Blue events are consistent with correct  $D^0$  reconstruction with the RS  $K\pi$  mass  
 Red events are consistent with correct  $D^0$  reconstruction with WS  $K\pi$  mass  
 Green: other backgrounds

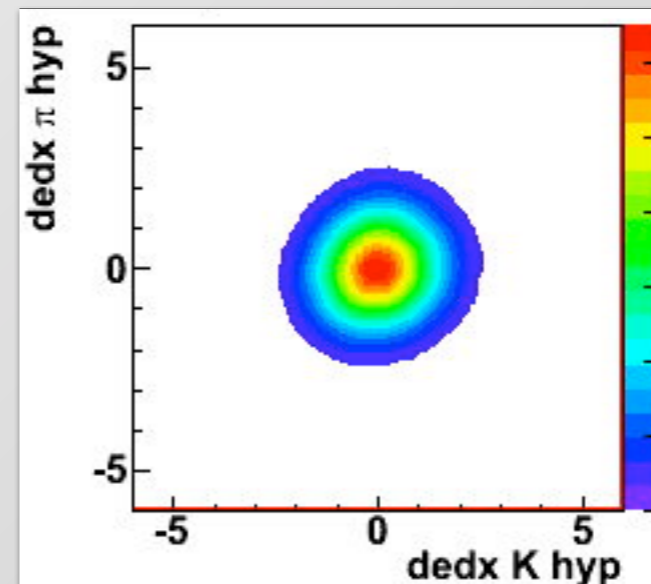

- Problem: Huge number of CF  $D^*$  (RS) events can mask WS signal
- Swapping the  $K\pi$  particle assignments causes the distribution to get x10 wider than the correct assignments

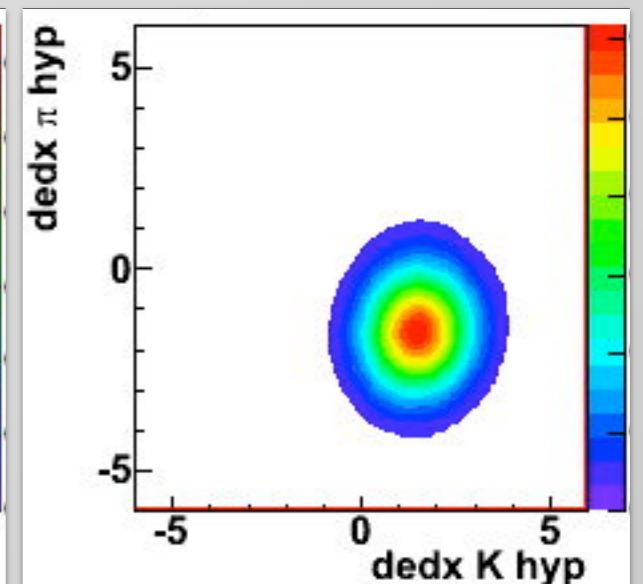

# dE/dX Selection

- Correct particle assignment for a track results in the dE/dX part. id. variable having a Gaussian distribution with mean=0, width  $\sim 1$ 
  - COT pulse height minus prediction for that type of particle, divided by error
- Incorrect assignment shifts the distribution away from zero
- Use both track part. id. at same time
  - Get “displacement” from zero,
  - Compare  $K\pi$  and  $\pi K$  track hypotheses, and keep the one closer to zero.

correct particle assignment

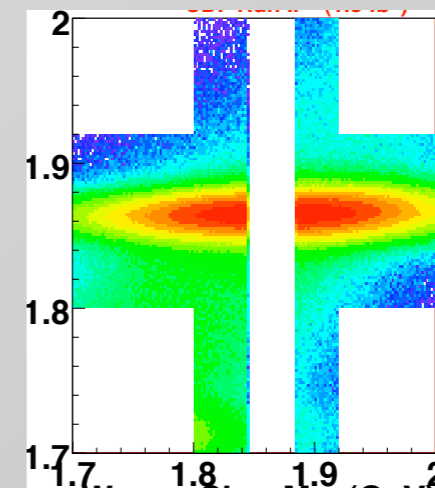

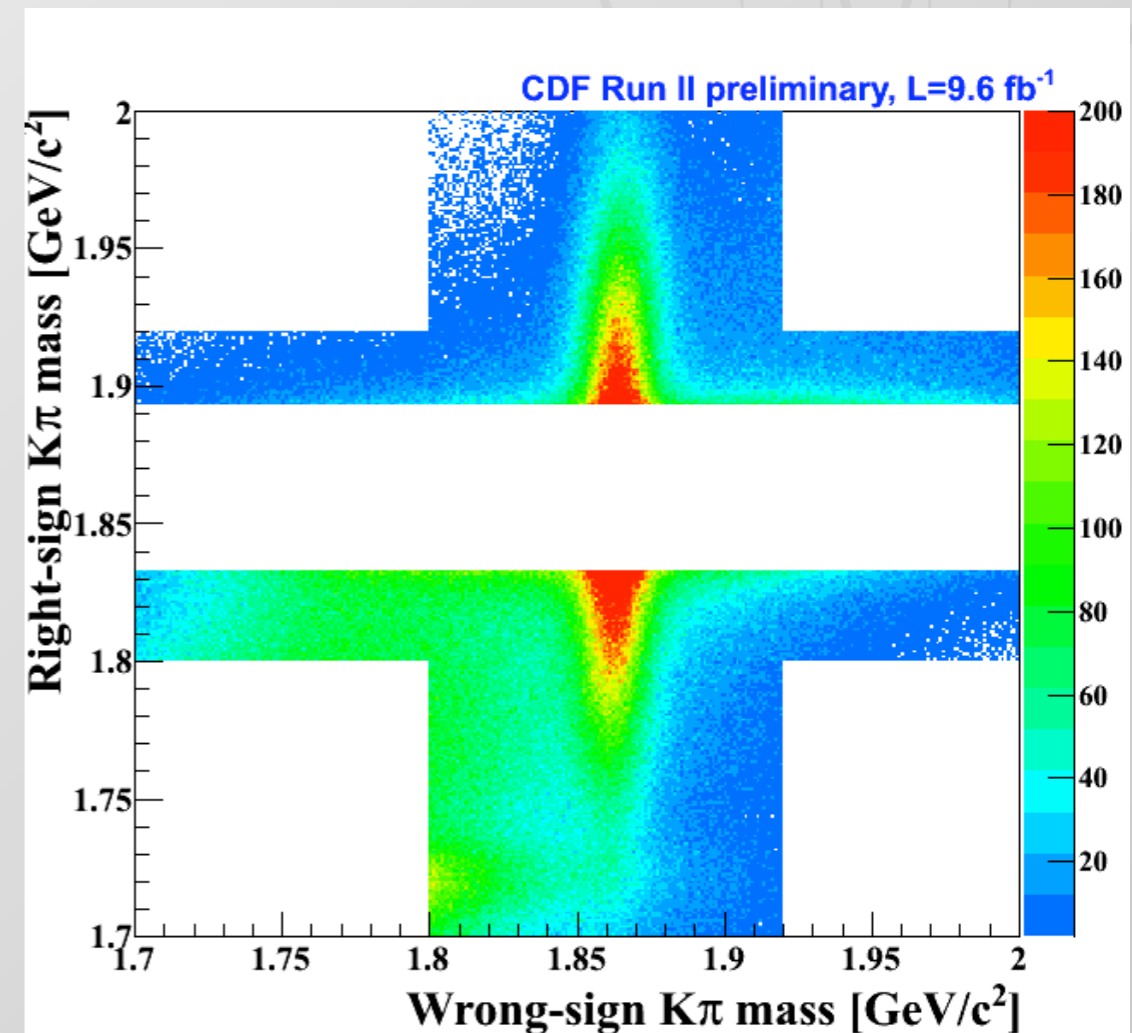

particles swapped

# WS, RS Selection

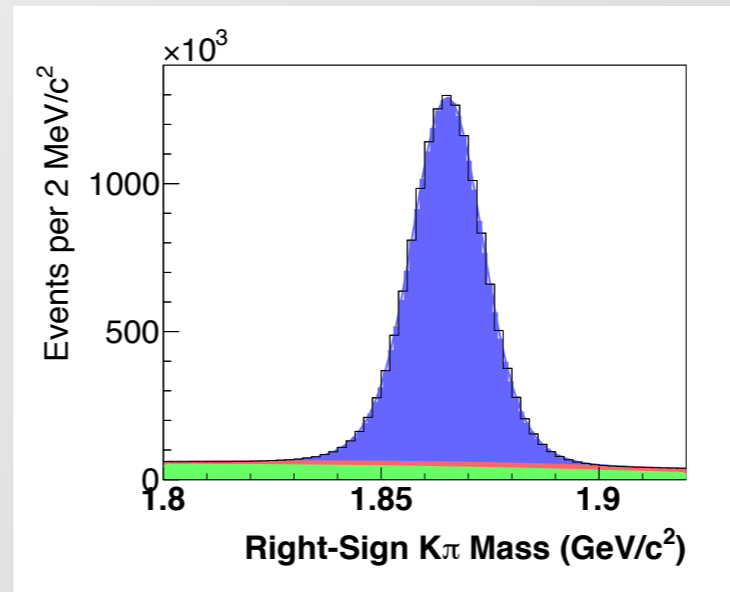

- When projecting the WS mass, exclude candidates consistent with being a RS  $D^0$ 
  - RS mass  $|m_{K\pi} - m_{D^0}| < 20 \text{ MeV}$
  - Reduces signal by 1/3rd, but only a few % of background survives
- Exclude candidates consistent with WS  $D^0$  when projecting the RS mass

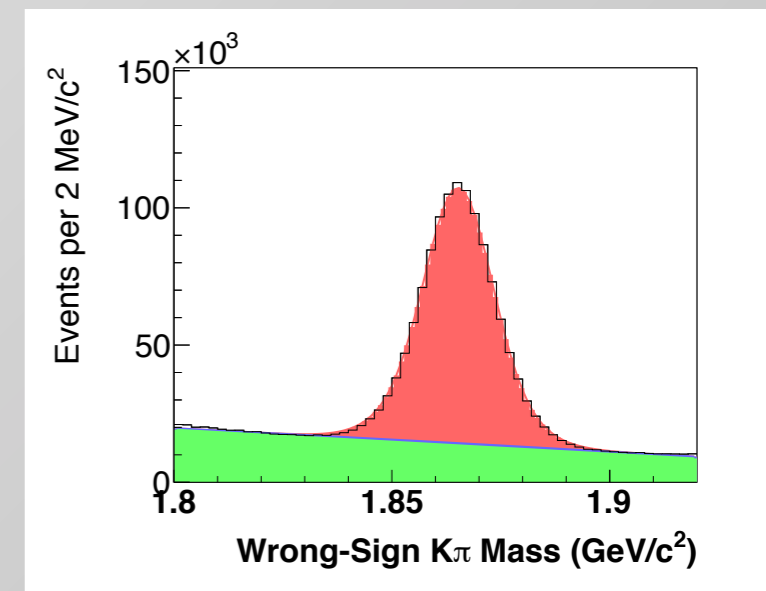

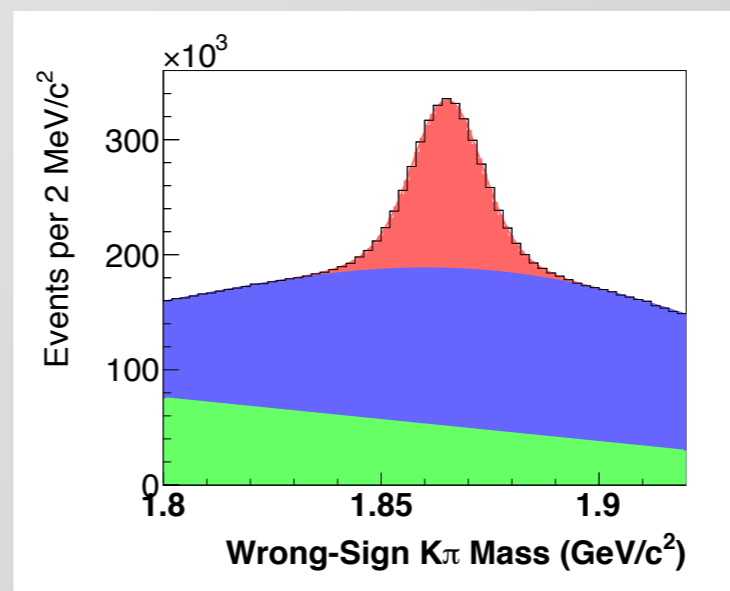

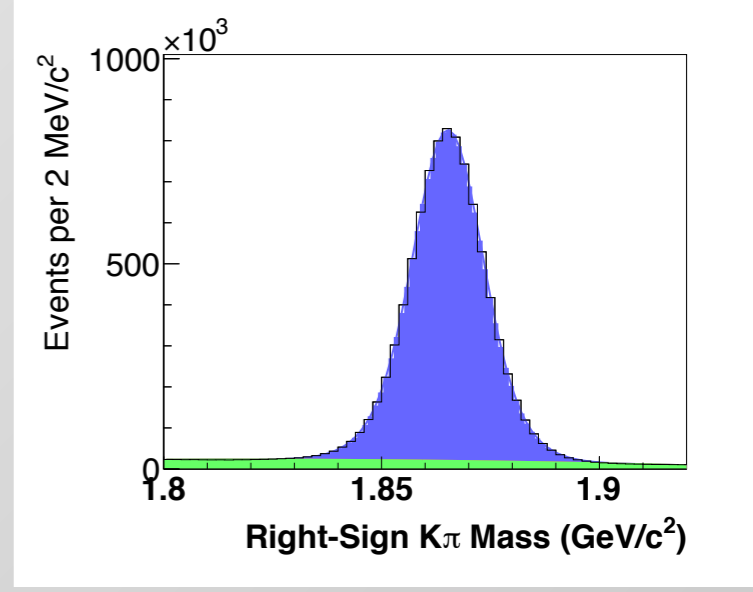

# Mis-Assigned Clean-up

- Mass and PID cuts greatly clean up the CF  $D^*$  background in the WS mass plots
- Sig/back improved  $\sim 120$ 
  - Blue events are consistent with CF (RS)  $D^*$  decays
  - Red events are WS  $D^*$ , and background from fake  $D^*$  ( $D^0$  + random track)
  - Green events are background

Before selections

After selections

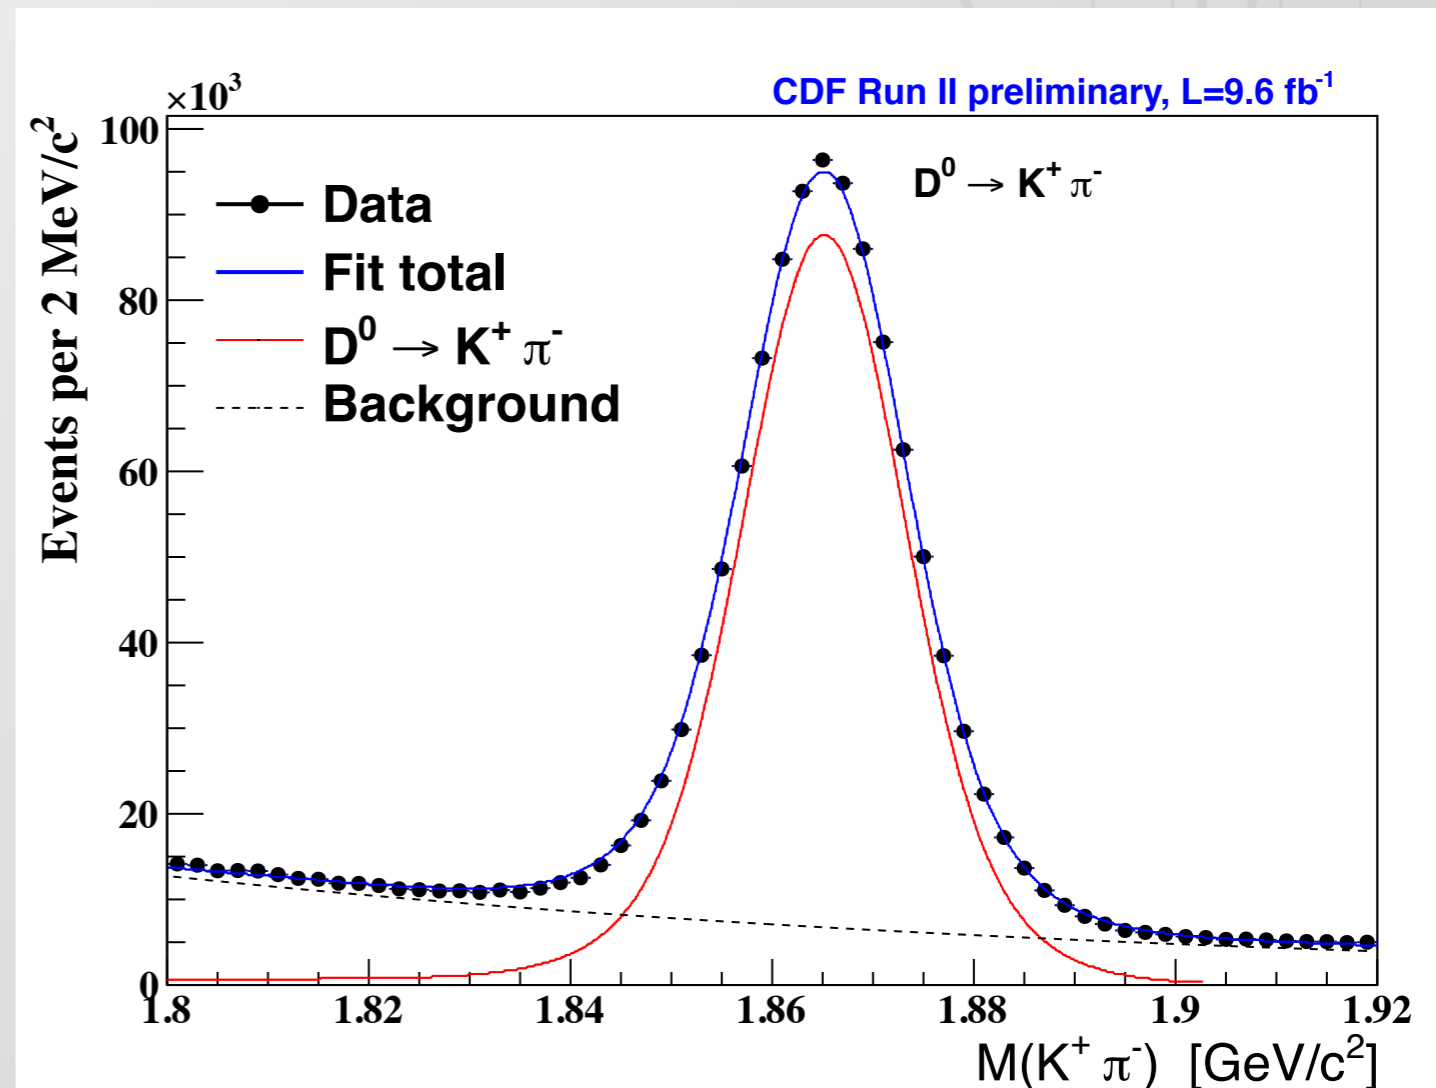

# Fitting Methods

# Analysis Overview

- Backgrounds to be accounted for
  - $D^*$  from B decays (not produced at beamline)
    - Make a correction in ratio  $R(t)$  to correct for the incorrect decay time
  - fake  $D^*$  candidates
    - Fit  $\Delta M$  plots to distinguish from real  $D^*$
  - fake  $D^0 \rightarrow K\pi$  candidates
    - Fit  $K\pi$  mass plots to distinguish from real  $D^0$
- Start at the bottom and work towards the top
  - Each successive step has fewer backgrounds to worry about

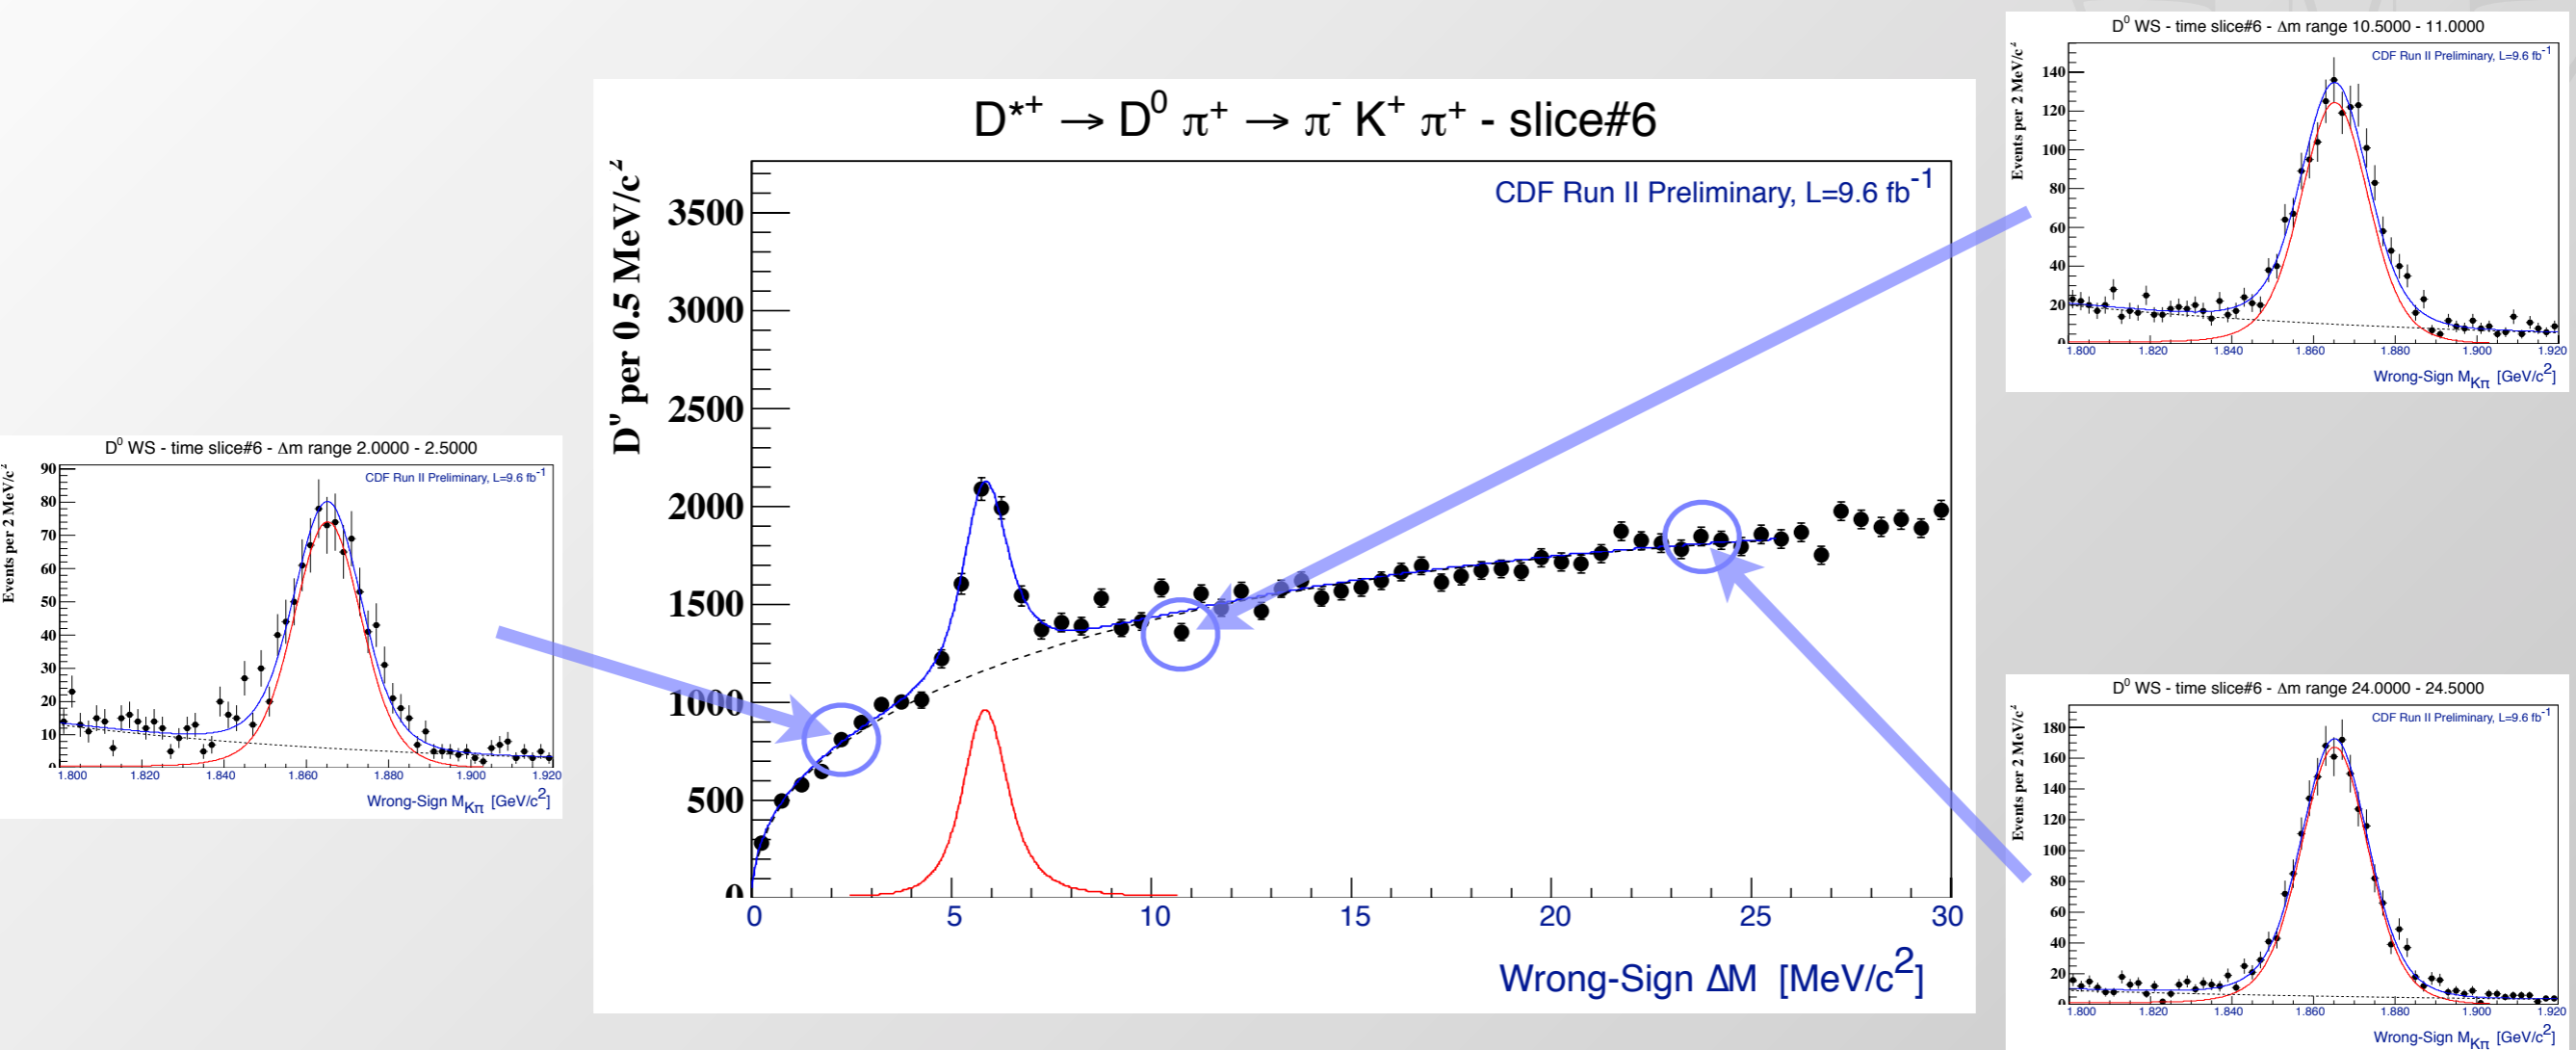

# $K\pi$ Mass Fits

- Only correctly reconstructed  $D^0 \rightarrow K\pi$  forms a peak in the  $K\pi$  mass distribution
  - Backgrounds can be fit with an almost flat curve
- 2400 mass fits
  - data divided into: RS, WS; 20 time bins; 60 bins of  $\Delta M$
- Same  $D^0$  signal shape used for RS and WS
- Parameters for background are independent for all fits

WS  $K\pi$  mass, time and  $\Delta M$  integrated  
(for illustration purposes)

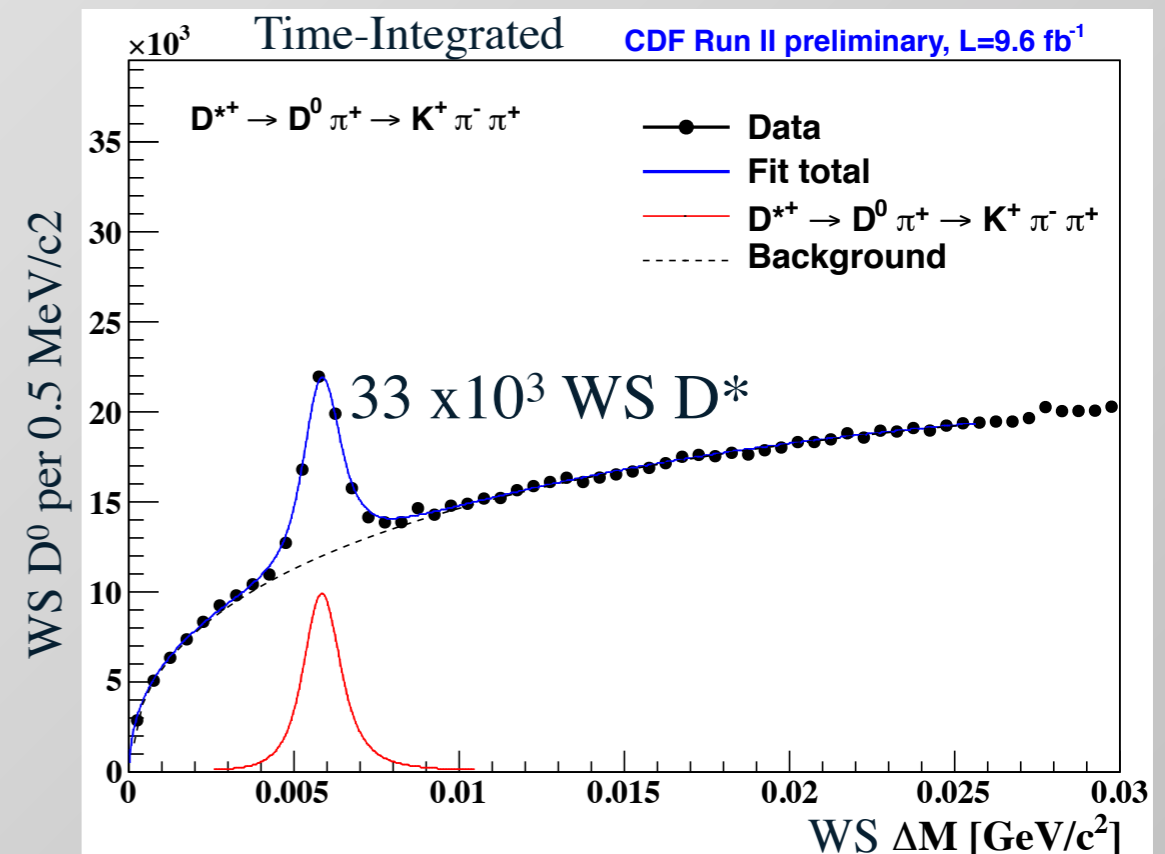

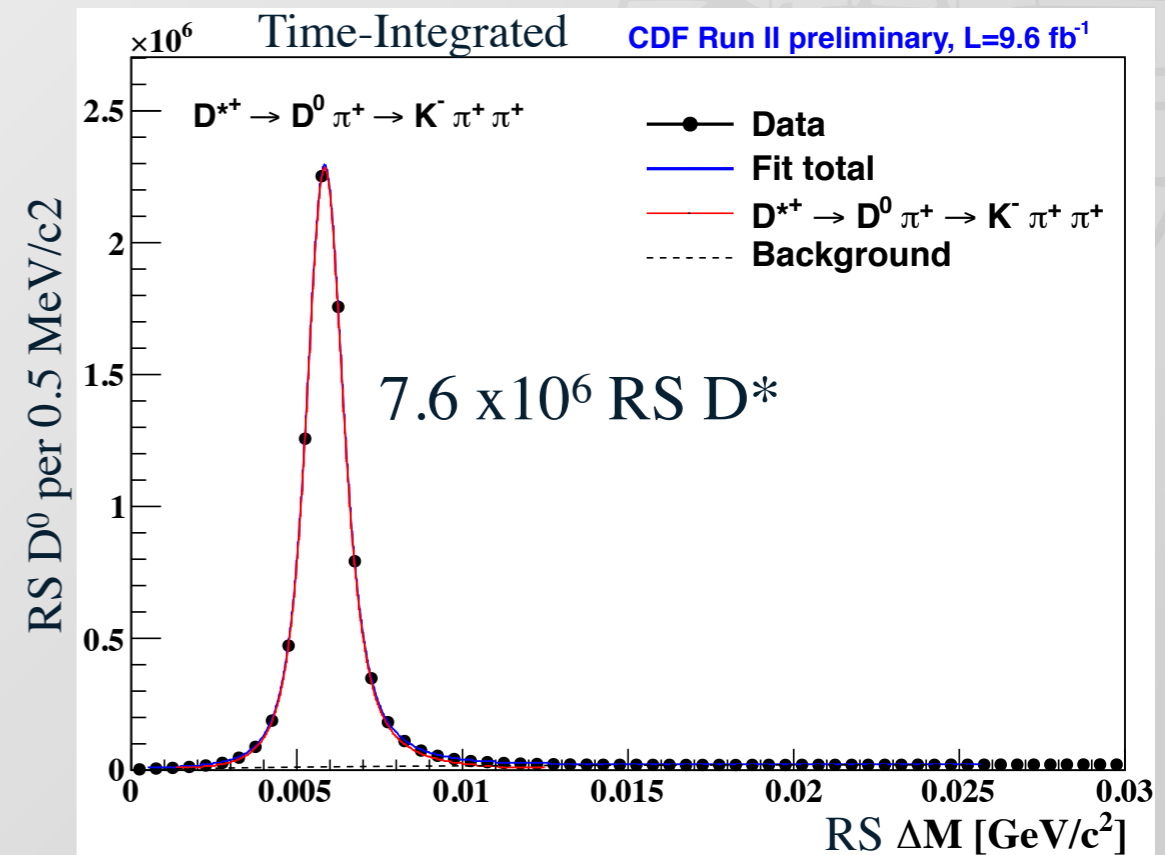

# Mass Diff. Yields

- Use results of the  $K\pi$  fits to get  $D^0$  versus  $\Delta M$  distribution
  - each point  $\rightarrow$  number of  $D^0$  from a  $K\pi$  fit
  - error bars are the uncertainty on # of  $D^0$  from  $K\pi$  fit

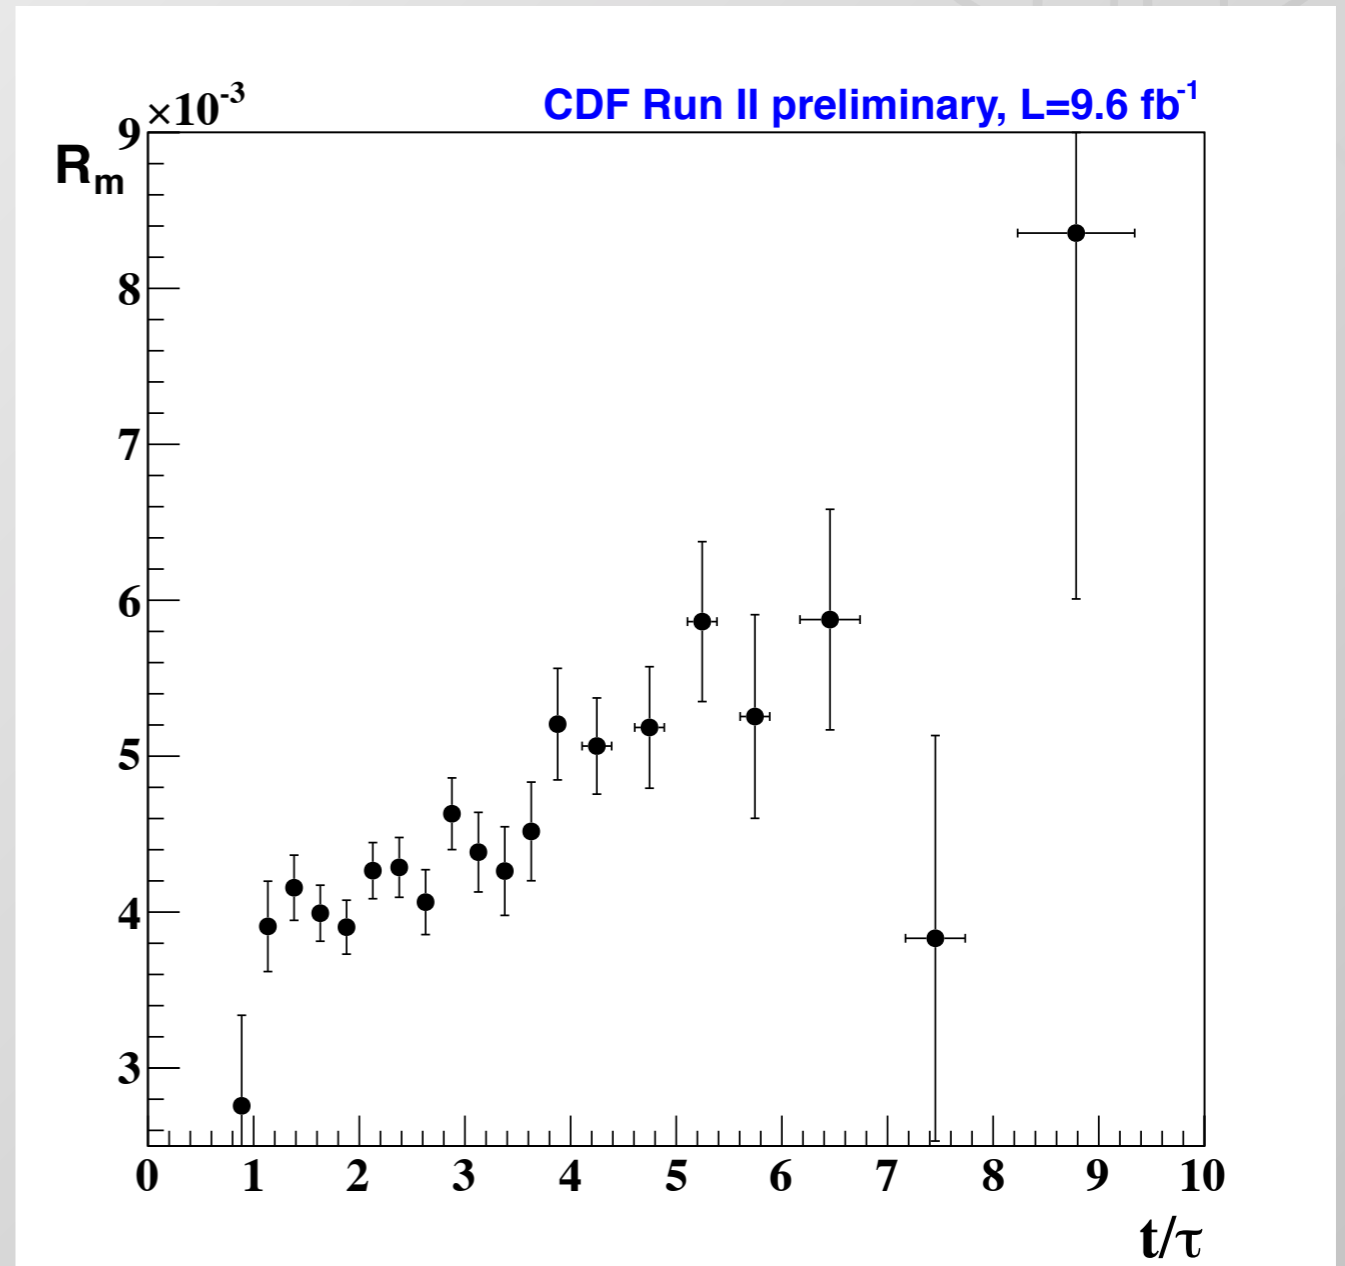

# $\Delta M$ fits

- 40 fits for  $D^*$  yield
  - RS, WS; 20 time bins
- RS and WS  $D^*$  have the same signal shapes
- Independent parameters for signal and background amplitudes for all time bins
  - Only events in these plots are  $D^*$  and ( $D^0$  + random track)

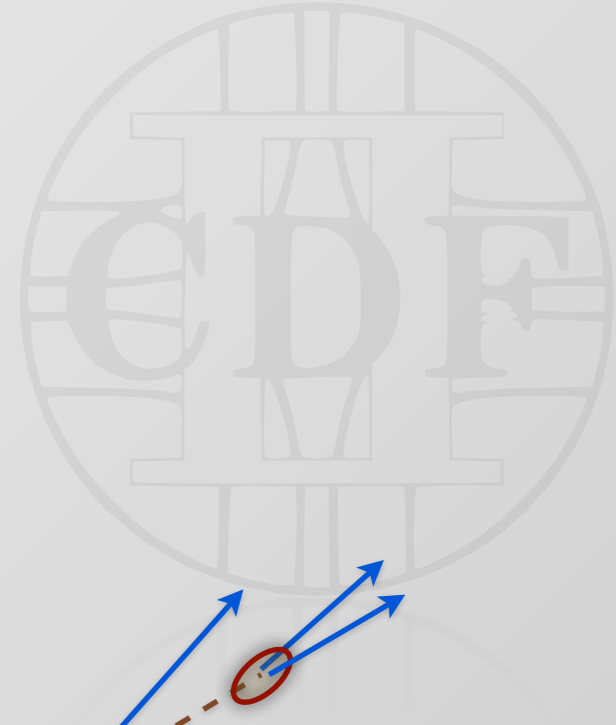

# WS/RS Ratio

- Use the 20 RS  $D^*$  yield and 20 WS  $D^*$  yield plots to get the WS/RS ratio in our time bins
- Some of these  $D^*$  were produced at the beamline
- Some of these  $D^*$  were not produced at the beamline
  - Decay time measured from the beamline will be incorrect
- Want to correct for the effect of these events on the WS/RS ratio

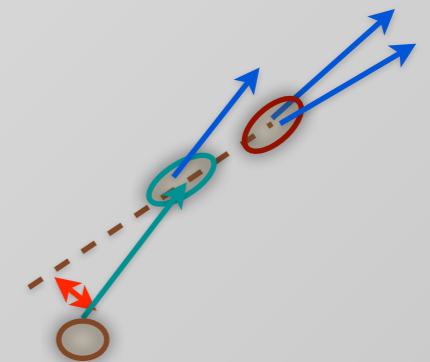

# Secondary $D^*$

- $D^*$  produced from B-decays will have the wrong proper decay time
  - decay length is measured from the primary vertex to the  $D^0$  vertex
  - Since the B lifetime to D lifetime is  $\sim 4:1$ , most of these background  $D^*$  will be short decay-time  $D^0$  shifted to longer analysis time bins
- Extrapolate the  $D^0$  towards the primary vertex
  - $d_0$  : impact parameter
  - $D^*$  produced at a secondary vertex will have a larger  $d_0$  value

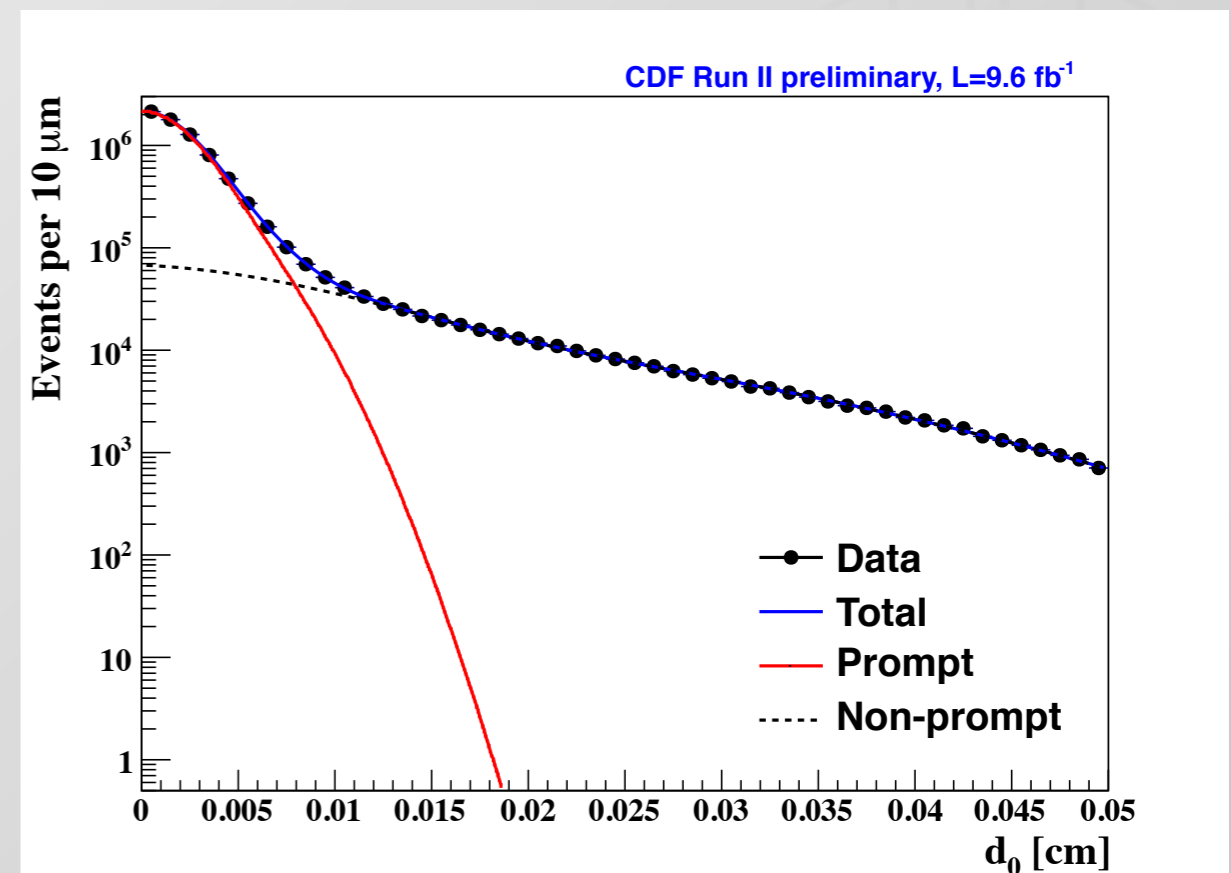

$D^*$  produced at the beamline  
33  $\mu\text{m}$  beam spot size

$D^*$  from B decay  
Decay length from beamline  
is longer than the  $D^0$  decay length

# Impact Parameter

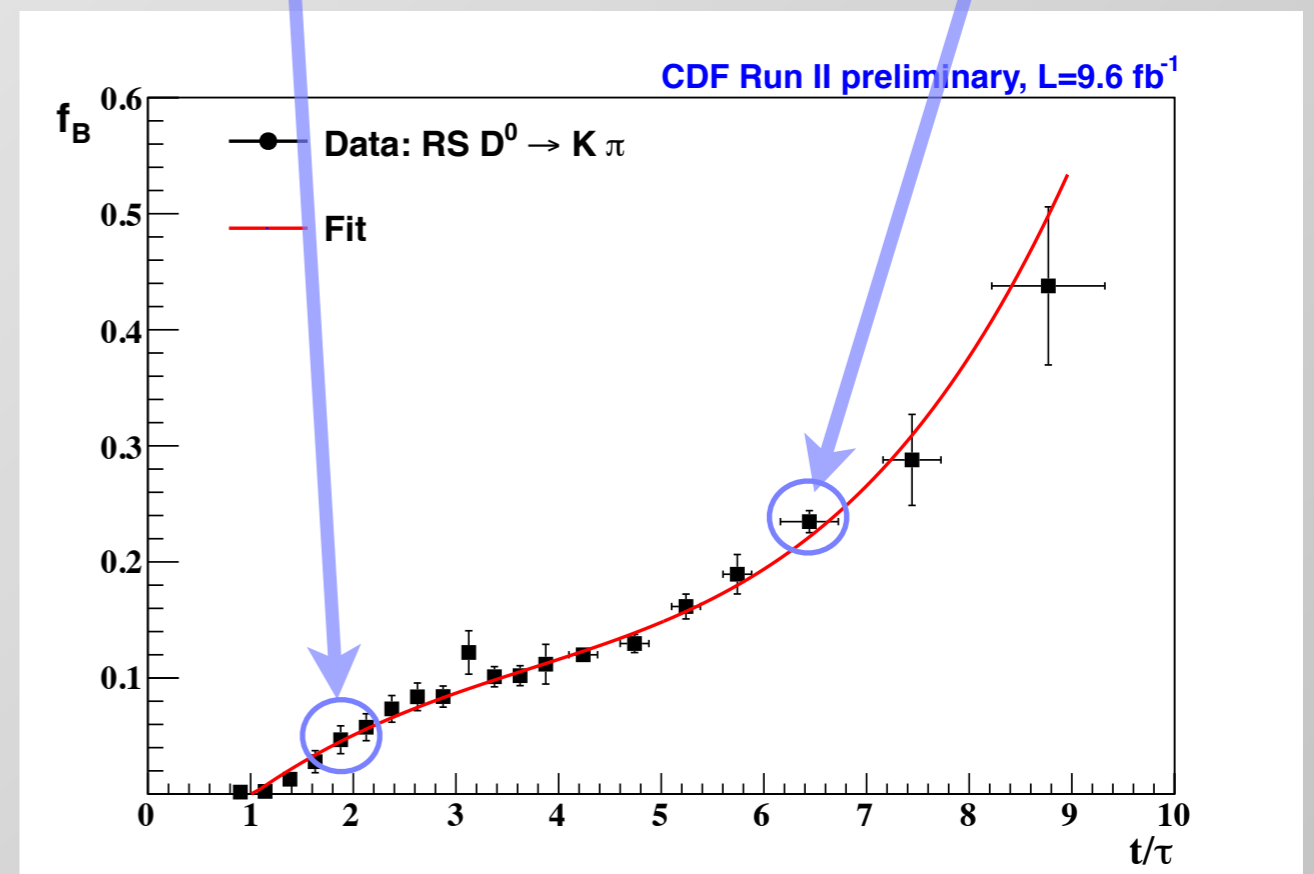

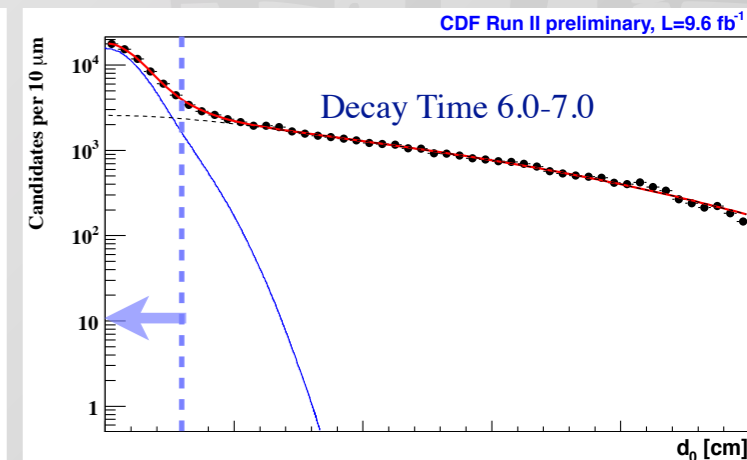

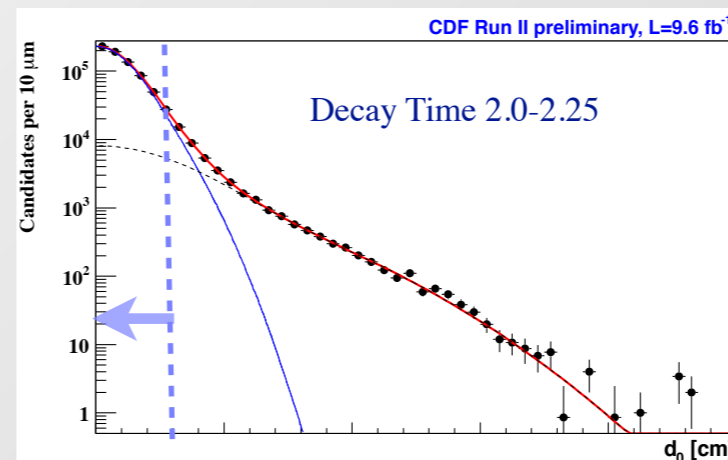

- $D^*$  produced at the primary vertex have a narrow, time-independent impact parameter ( $d_0$ ) distribution
  - confirmed with data and MC
- $D^*$  from B decays have a wider, time-dependent distribution
  - width increases with decay time
  - fit distribution using RS signal

Time-integrated RS distribution

# Impact Parameter

- For each analysis time bin, fit the prompt and non-prompt distributions
- prompt-shape: double Gaussian
- non-prompt: double Gaussian, each time bin is independent of the others
- Use these fits to determine  $f_B(t_i)$ , the fraction of RS  $D^*$  (with  $d_0 < 60 \mu\text{m}$ ) that come from B-decays
- Fit with 4th-order polynomial (empirical)

# Secondary WS/RS Ratio

$$R_B(t_i) = \frac{\sum_{j=1}^M \tilde{h}_{ij} R(t'_j)}{\sum_{j=1}^M \tilde{h}_{ij}}$$

- Use MC simulation to get the WS/RS ratio  $R_B$ 
  - For each analysis time bin ( $t_i$ ), get the distribution  $h_{ij}$  of  $D^0$  decay times, if we knew the B to the  $D^0$  decay time ( $t'_j$ )
  - Use the predicted ratio formula  $R(t)$ , but with the “correct” time ( $t'_j$ ) for this type of background

$$R(t/\tau) = R_D + (t/\tau) \sqrt{R_D} y' + (t/\tau)^2 \frac{x'^2 + y'^2}{4}$$

# WS/RS Fit $\chi^2$ Function

Instead of comparing the data points directly to the predicted ratio formula...

$$\chi^2 = \sum_{i=1}^{20} \frac{1}{\sigma_i^2} (R(t_i) - r_i)^2$$

$$R(t) = R_D + (\Gamma t) \sqrt{R_D} y' + (\Gamma t)^2 \frac{x'^2 + y'^2}{4}$$

... use the formula that includes  $D^*$  background from secondary decays.

ratio prediction: includes contribution from  
“beamline” and “B decay”  $D^*$

term for uncertainty on the  
MC time distribution

$$\chi^2 = \sum_{i=1}^{20} \frac{1}{\sigma_i^2} ((1 - f_B(t_i)) R(t_i) + f_B(t_i) R_B(t_i) - r_i)^2 + C(f_B) + C(h_{ij})$$

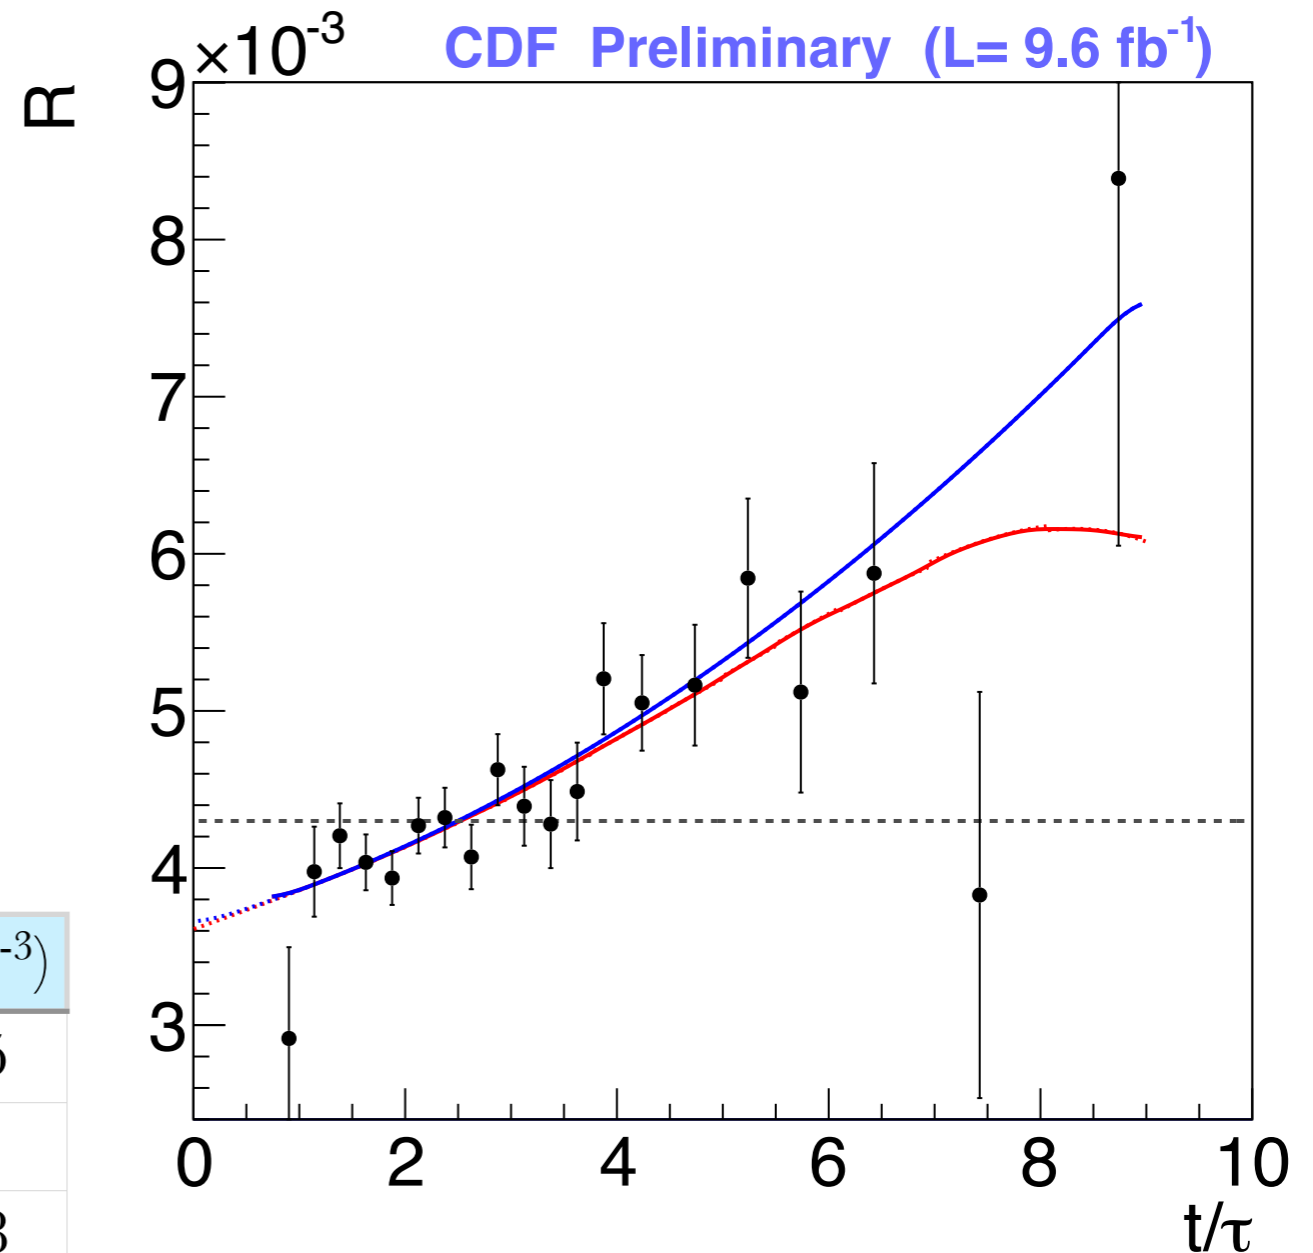

term for the uncertainty on the secondary fractions  $f_B$

# Systematic Studies

- The uncertainties stated includes the errors returned by the mass fits and uncertainties on the fractions  $f_B$  and the simulation time distributions.
- Investigated possible effects that could bias the result
  - Variation of  $D^0$  signal shape
  - $D^*$  signal shape
  - partially reconstructed charm background in  $K\pi$  fits
  - $D^*$  background shape
  - impact parameter non-prompt shape
  - simulation time scale
  - detector track reconstruction asymmetries
- The systematic uncertainties were found to be small relative to the statistical errors from data
- For many of these, there is a common effect on the WS  $D^*$  and RS  $D^*$  fits, and the effect cancels in the WS/RS ratio

# Ratio Result

- Dashed line is the fit assuming no-mixing (no time dependence)
- Red line is the fit including the contribution  $D^*$  from secondary decays
- Blue is the projection of the parameters, if there were no  $D^*$  from B-decays

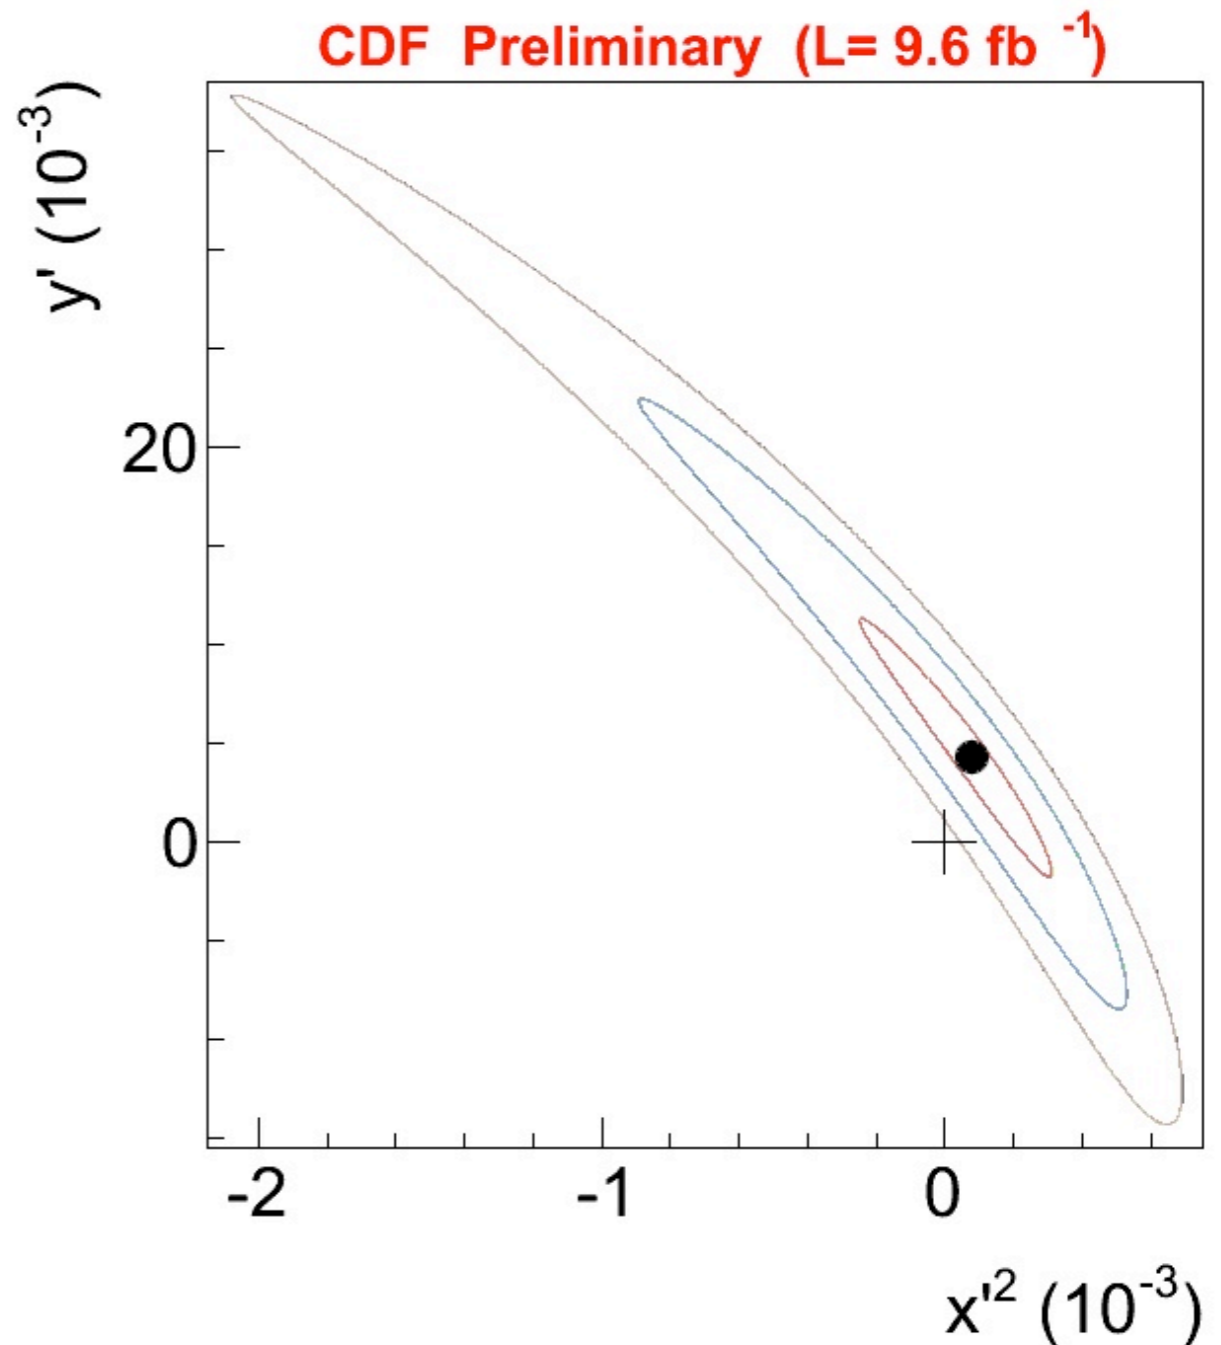

Fit Type	$\chi^2$ /ndof	Parameter	Fit Value ( $10^{-3}$ )
		$R_D$	$3.51 \pm 0.35$
Mixing	16.91/17	$y'$	$4.3 \pm 4.3$
		$x'^2$	$0.08 \pm 0.18$
No-mixing	58.75/19	$R_B$	$4.30 \pm 0.06$

Correlation Coefficients		
$R_D$	$y'$	$x'^2$
1	-0.967	0.900
	1	-0.975
		1

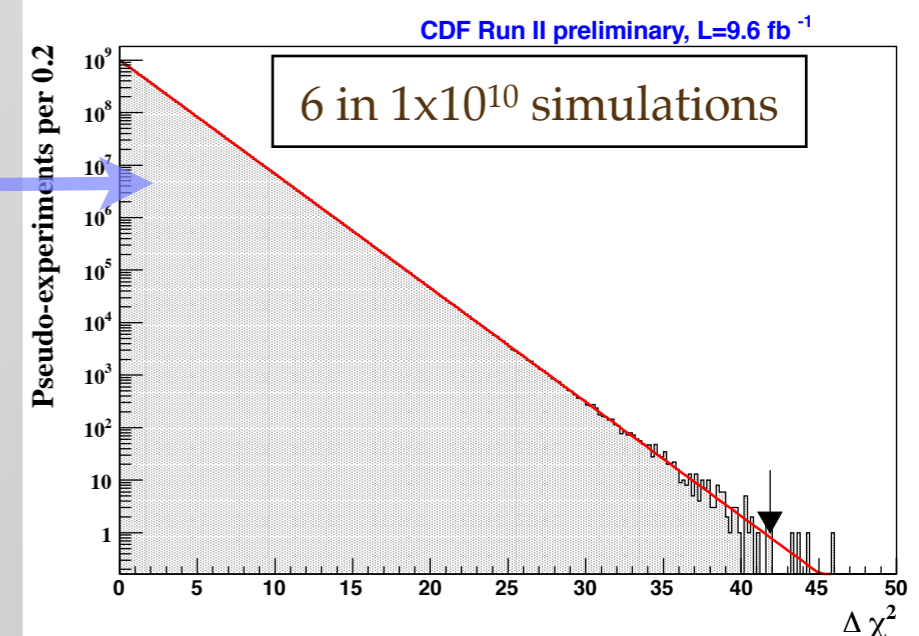

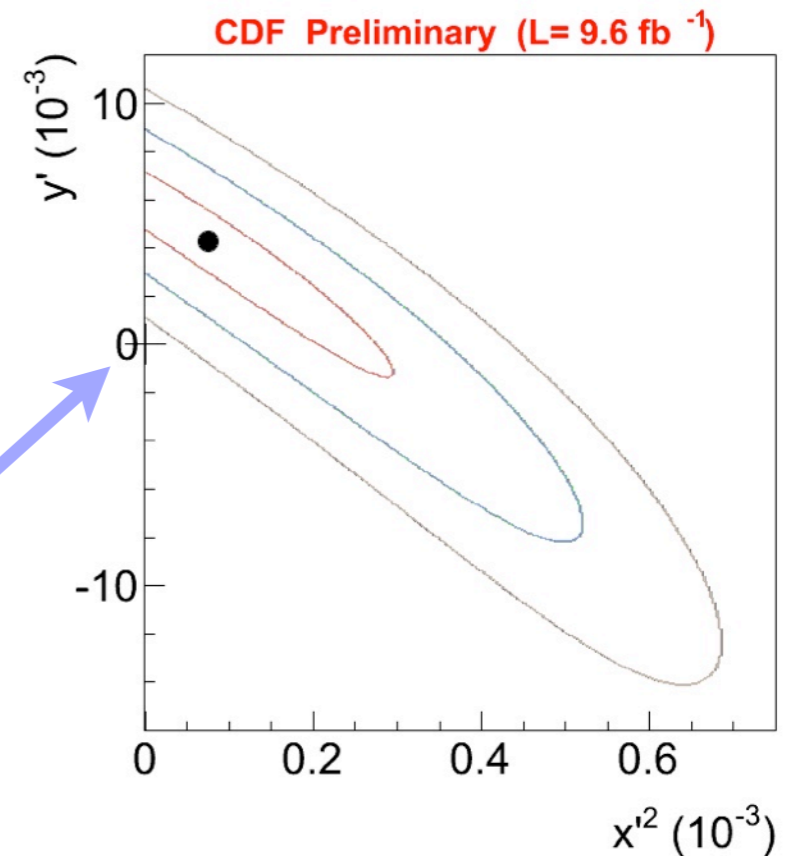

# Probability Contours

- Bayesian probability intervals equivalent to 1, 3, and 5  $\sigma$ 
  - likelihood  $\sim \exp(-\chi^2/2)$
  - solid point = best fit
  - cross = no-mixing ( $y' = x'^2 = 0$ )
    - $x'$  is a real number, so fits with  $x'^2 < 0$  are unphysical
- Bayesian probability contour that excludes no-mixing point is equivalent to  $6.1\sigma$

# No-mixing Significance

- Alternative checks of the significance
- All resulted in exclusion at  $6.1\sigma$  significance
  - Bayesian probability restricted to  $x'^2 \geq 0$
  - Probability for  $-2\Delta\log(L) = 41.8$ , between best fit and no-mixing point, assuming  $\chi^2$  distribution with 2 d.o.f.
  - p-value (frequentist): Number of toy simulations with  $\Delta\chi^2 \geq 41.8$

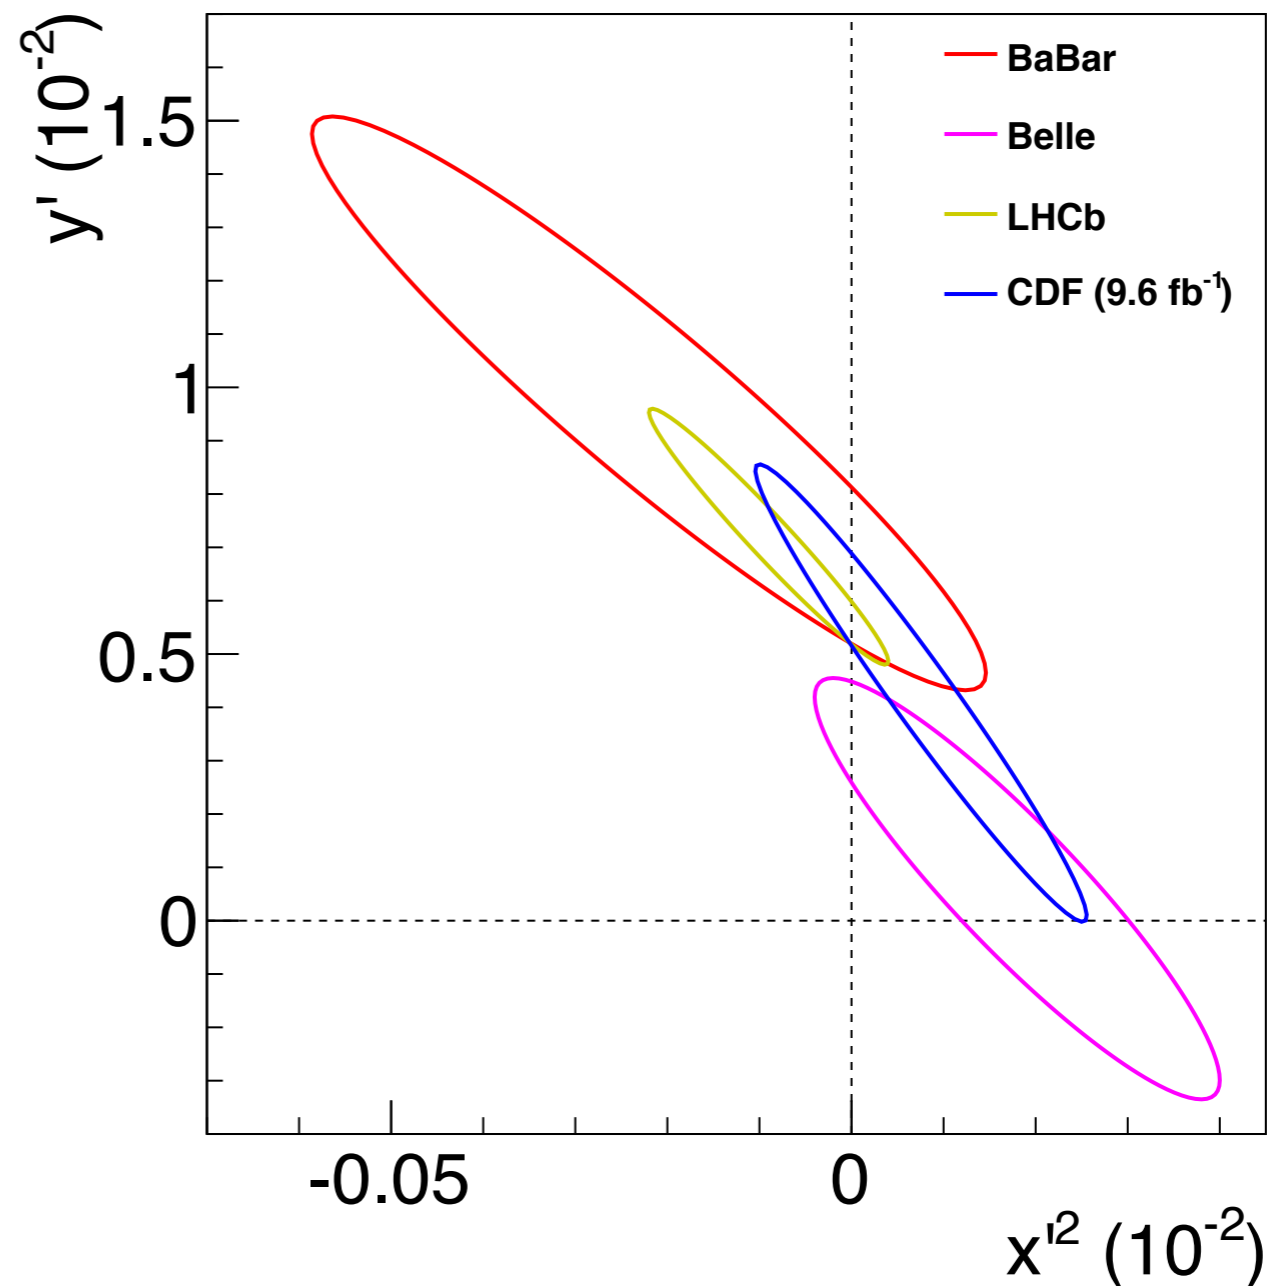

# Experiment Results

Experiment	$R_D$ ( $\times 10^{-3}$ )	$y'$ ( $\times 10^{-3}$ )	$x'^2$ ( $\times 10^{-3}$ )	Excl. No-Mix Significance	$R_B$ ( $\times 10^{-3}$ )
<b>Belle (2006)</b>	$3.64 \pm 0.17$	$0.6 \pm 4.0$	$0.18 \pm 0.22$	2.0	$3.77 \pm 0.09$
<b>BaBar (2007)</b>	$3.03 \pm 0.19$	$9.7 \pm 5.4$	$-0.22 \pm 0.37$	3.9	$3.53 \pm 0.09$
<b>LHCb</b>	$3.52 \pm 0.15$	$7.2 \pm 2.4$	$-0.09 \pm 0.13$	9.1	$4.25 \pm 0.04$
<b>CDF (9.6/fb)</b>	$3.51 \pm 0.35$	$4.27 \pm 4.30$	$0.08 \pm 0.18$	6.1	$4.30 \pm 0.06$

- In this table, “ $R_B$ ” (PDG notation) means the fit assuming no-mixing (or the time-integrated ratio).
- “ $R_D$ ” is the parameter for the mixing fit, for the ratio at  $t=0$

# Mixing Comparisons

- Difficult to get full contours from all experiments
- As an approximation, make  $1\sigma$  contours based on the fit parameters errors and  $y'-x'^2$  correlations

# Conclusion

- We measured charm mixing in the  $D^0 \rightarrow K\pi$  channel using the full CDF data set
- We confirm LHCb observation of charm mixing (from a single decay channel measurement)
- CDF measurement contributes important statistical precision to mixing parameters
- New physics may emerge from future precision measurements combined with advances in theory
